Much learned discussion has been indulged in as to the therapeutic value of heliotherapy based upon the percentage and intensity of the contained Dorno rays, *i.e.*, wavelengths between λ289 mμ.

and λ313 mμ. which happen to lie in the ultraviolet.

Granting the preëminent value of the Dorno rays, no one has established the minimum dosage necessary, *i.e.,* the area to be exposed and the intensity and time factors, to maintain health or to restore it in such cases, for example, as rickets.

Tables of sunshine hours per year and charts showing the proportion of Dorno radiation in the total of solar rays in various latitudes and seasons and time of day and under various atmospheric conditions are all of slight value until we have this minimum dose established. Hess has shown that New York has more sunshine annually than Havana, and also more rickets. If the Dorno rays were so essential because of their influence upon calcium and phosphorous utilization why they could be satisfactorily replaced by doses of viosterol. But viosterol does not satisfactorily replace the chemical rays.

Exposure of the nude body is highly desirable to bring about all of the influences which tend to restore to the skin its natural functions and especially that of heat regulator for the body. This exposure should be accompanied by weathering, that is, exposure to currents of air in the open under the sky.

This double exposure requires a careful preparatory regime of weathering and pigmentation in gradually increasing doses and by all means without sunburn or chilling. Those unable to pigment may take their sunbaths in the early morning or late afternoon, when chemical radiation in the Dorno region is mitigated so as to avoid sunburning.

Based upon the value of the Dorno rays a special glass has been invented which permits their passage unobstructed. It is recommended for window panes in lieu of ordinary glass, which obstructs these rays.

This special glass finds its greatest usefulness in buildings where people are confined during most of the daylight hours. It does not create the Dorno rays and therefore it does no good on cloudy days nor in smoky, dusty atmospheres nor if it is coated with a film of dirt. It is valuable only when crystal clear and when receiving the pure direct rays of the sun, preferably from the zenith and in the south. It is partially effective when receiving skyshine and cloud light from a northern sky. The same value is to be placed upon quartz panes which are now being produced at a price which makes them available. Also cellophane is transparent to the Dorno rays.

Although the solar radiation shows such variability in intensity and quality it is nevertheless potent in very small doses but there are many, many persons of all ages whose daylight hours, especially those most potent in chemical rays, are spent indoors and in interiors artificially illuminated.

We are now able to obtain artificial solar rays both for therapeutic use and for prophylactic use. These with the use of selected metallic reflectors and the proper reflecting paint on the walls and ceilings, produce a very satisfactory substitute for sunrays. When employing them in heliotherapy the feature of weathering should also be included.

The oldest type of heliotherapeutic lamp is the Brush electric arc lamp. This is more familiarly called the carbon arc lamp. It has three variations. The open arc, the open arc with reflector (such as the marine searchlight and the ordinary therapeutic arc lamp) and the enclosed arc.

The enclosed arc lamp was originally a German lamp called the Efkaheliol lamp and sold in America as the Hoffman. It has been modified in this country by Luckenbach and Hallberg so that it can be used either as an open or enclosed arc. It is a safe lamp to use in family practice as it emits no fumes and can be operated by a d.c. or a.c. supply.

The carbon arcs can be obtained in any desired wattage and in many different designs. It must be borne in mind that it is the substance of the electrode which produces the spectrum and the wattage at which the lamp operates which governs the intensity. To pay six hundred dollars for a fancy stand and a lot of large metallic reflectors and funnels surrounding a carbon arc which operates at the same wattage as an eighty-five dollar lamp advertised for photographic purposes is certainly not the act of one well informed. The wattage and the substance of the arc points are the essence of the therapeutic value of Brush arc lamps.

The National Carbon Company makes electrode points of special composition which when burned in the arc emit very distinct variations of the spectrum. One may therefore by changing the electrodes give a photochemical treatment in the Dorno region or in the visible region or a thermal treatment in the caloric region or an artificial heliotherapeutic treatment with a sunlight spectrum.

If one desires to give photochemical treatments locally or orificially from the carbon arc lamp then the Gelb-Finsen arc lamp with a special water-cooled attachment for quartz applicators is a standard when employing the various types of electrodes.

The second type of heliotherapeutic lamp is the superheated tungsten filament electric lamp in a special globe of very thin glass which is transparent to the shorter ultraviolet wavelengths, especially the Dorno region. The spectrum emitted resembles very closely that of the summer sun and contains more of the ultraviolet portion of the chemical rays than that from the mercury vapor arc in quartz when compared wattage for wattage.

One variety of this lamp is called the Curay.

It is a hand lamp and when fitted with a quartz applicator it gives directly photochemical rays of the same part of the spectrum as the Krohmayer lamp when the methylene blue filter is used to cut off the irritating small wavelengths It is not only valuable for giving soothing photochemical treatments but makes an excellent source of trans illumination for diagnosis When fitted with a Corex glass filter it can be used for diagnosis by *fluoroscopy*

The other variety of filament lamp for helio therapy is the large floor or ceiling lamp with reflector, called the Polysonn, which comes to us upon the recommendation of Prof Dannmeyer, from Germany

The third type of heliotherapeutic lamp is the recently presented General Electric Company's Sunlight (Type S-1) lamp Its spectrum resembles that of the noon summer sun and does not contain the short irritating wavelengths in the ultraviolet found in the mercury spectrum because of its glass bulb, although it emits a mercury spectrum

The bulb of this lamp resembles a large sized Mazda When the current passes it heats the v shaped filament which vaporizes some of the contained mercury The vapor of mercury conducts the current across a small gap between two tungsten electrodes which strikes an arc The resulting radiation is the combined emission of incandescent tungsten, mercury vapor ionized and the incandescent filament

Owing to the high temperature at which it operates it requires that an alternating current be stepped up by a transformer It is possibly the best substitute for sunlight for heliotherapy both for office and institutional use and is ideal for family use

With the sun or any of its substitutes it is possible to administer purely photothermy by merely interposing a transparent colorless glass filter It is possible similarly to filter out the caloric rays leaving only the chemical rays in the ultraviolet region by using filters of Wood's glass or Corex glass or water lenses of quartz as Finsen did

Scientific phototherapy can no more be used indiscriminately by the untrained or the general public than any other remedy since it is fraught with dangers and unhappy results On the other hand it is a very valuable form of treatment and particularly complimentary to all other forms of therapeutics

A REPORT OF TWO CHEST CASES WITH FEATURES OF SPECIAL INTEREST

By MILTON SILLS LLOYD, M D, NEW YORK, N Y

CASE 1

A Case of Mediastinal Suppuration With Recovery After Spontaneous Drainage Into the Trachea

SUPPURATION in the mediastinum, secondary to the perforation of the trachea or oesophagus, by a foreign body is a common enough occurrence and is generally considered as a fatal complication As a sequel to disease in the lung, it is infrequently seen and is to say the least an unsatisfactory surgical problem

The following case, because of its course and outcome is of interest

A white male, aged 37 years, was the victim of pneumonia in the middle of February, 1930 Since three people in the same household were afflicted, at the same time, both influenza and psittacosis were suspected, but there was no evidence to support a diagnosis of either of these conditions The temperature fell by lysis and after about two weeks' illness, the patient appeared to have made a satisfactory recovery No X Ray photographs of the chest were made

After five days convalescence, there was a return of chills, sweats and fever The patient gradually became worse and was admitted to the Staten Island Hospital on March 15th Seen at that time, he was weak and pale, sweating profusely, with a temperature of 102°F, pulse 120 (irregular) respirations 40 and a cough, productive of 1½ ozs in 24 hours Physical examination of the chest indicated fluid at both bases posteriorly, a small area of consolidation at the angle of the right scapula and a considerable enlargement of the heart There were large rales and medium ronchi over the right base anteriorly White blood cells numbered 14,800 per cu mm Sputum blood and urine examinations revealed no other information of importance An X-Ray was taken, on admission and a diagnosis of mediastinal effusion was made Attempts were made to aspirate the chest on three occasions but no fluid was obtained On March 20th a thoracic surgeon

was called in consultation. He refused to operate, however, because of the resemblance to a mediastinal New Growth.

The patient's condition gradually became worse, until March 27, when death appeared to be momentarily impending. During the night, he was seized with a sudden attack of coughing and raised a large quantity of creamy, greenish-yellow, homogeneous and structureless purulent material. His sputum in the next 24 hours amounted to 11ozs. but he was much improved, clinically, in every respect.

From that time on, his recovery was rapid and complete and he was able to return to his home in two weeks.

Before leaving the Hospital, he was asked to submit to a bronchoscopic examination, from a point of view of purely academic interest. He was sporting enough to do so. The examination showed a complete absence of pus throughout the tracheo-bronchial tree. On the left posterior wall of the trachea, about ¾ inch above the bifurcation was a small elevation, apparently composed of granulation tissue, which sank into the mediastinum, during inspiration and rose into the trachea, during expiration. Touched, with the point of a curved aspirator, the tissue was friable and bled easily and it appeared to be a simple matter, to push the tip through into the mediastinal space. Naturally, the patient was not exposed to this unnecessary risk.

The author believes, that he was correct in concluding, that this elevation, in the trachea, represented the partially healed perforation from which a mediastinal purulent collection had drained.

The author is indebted to Dr. H. A. Cochrane, for referring this case to him and for his permission to report it.

Case 2

Intrabronchial Tumor, Complicated by Interlobar Effusion

The writer feels, that the following case deserves to be recorded, in the literature, because it deals with certain features, in connection with intrabronchial new growths, which do not appear as yet to have been reported.

The patient, a white female aged 28 years, entered the Staten Island Hospital, on March 24, 1930, because she had expectorated blood, amounting to "about a pint." In the Hospital, shortly after her arrival, she coughed up a measured eight ounces of bright red blood. Her temperature was 102° Fahrenheit. On physical examination, there was limited movement on the right side, a small area of dullness and diminished breath sounds, at the right base, in the anterior axillary line and a loud purring ronchus, especially at the end of expiration over the right base anteriorly. Her W.B.C.'s numbered 11,000 per cu.mm. The sputum was negative for tubercle bacilli.

A lateral X-Ray revealed the presence of a small effusion between the right middle and lower lobes. About four c.c. of this fluid was obtained on inserting a needle into the area of dullness, previously described. It was clear, yellow and sterile on culture.

Bronchoscopic examination was recommended, but the patient hesitated to give her consent. She did, however, consent to an intratracheal injection of Lipiodol. The Lipiodol was accordingly injected, by the Catheter Method,[1] under direct fluoroscopic observation. The oil was seen to descend into the right bronchus, to about the midpoint, where it was completely arrested. It continued to accumulate, at this point, until the extreme phase of the inspiratory movement was reached, when it suddenly dropped to the bottom of the lung. There was evidently some type of valvular obstruction, in the right bronchus.

On March 31st, with the patient's consent, a bronchoscope was passed. The right lower lobe bronchus, was seen to contain a glistening, predunculated tumor, about the size and shape of a large bean, attached to the medial wall, about ⅜ in. below the mouth of the middle lobe bronchus. This tumor moved freely up and down with respiration. Its under surface was greenish and appeared to be necrotic. The mucous membrane of both the middle and lower lobe bronchi was severely thickened and inflamed. An attempt to remove the tumor, with cutting forceps was made, but on account of its tough resistant nature, and the danger of hemorrhage, was abandoned, to be re-attempted at a later date, with a specially constructed cautery.

About a week later a bronchoscope was passed a second time. The tumor was no longer present but the peduncle could be easily seen. A specimen of tissue was removed from it. After the examination, the patient stated, that two days previously, during a fit of coughing, she had brought up a "hard lump." Not realizing its importance, she had discarded it. On section, the tissue appeared "very suspicious of early squamous celled carcinoma of the bronchus."

The cough expectoration and fever immediately disappeared. An X-Ray about two weeks later, showed the complete disappearance of the interlobar effusion.

Six weeks later, following the delivery of a normal child, a second specimen of tissue was removed. The examination on this occasion showed "hypertrophy of the lining membrane of the bronchial mucous glands, but no evidence of malignancy."

DENTISTS AND STATE MEDICINE

By A. M. SIMONS, B.L., CHICAGO, ILL.

From the Committee on the Study of Dental Practice of the American Dental Association, Herbert E. Phillips, D.D.S., Chairman; R. E. Denny, D.D.S., H. J. Leonard, D.D.S., G. S. Millberry, D.D.S., and C. E. Rudolph, D.D.S., N. Sinai, D.P.H., Adviser.

Are We Facing Social Control of Sickness Treatment?: Call it "Sickness" or "Health Insurance," the "Panel System," or "State Medicine," no legislation has so greatly affected so many people as that for the social control of the treatment of disease. No section has been so deeply affected as the different branches of the professions dealing with the treatment of disease. This applies almost equally to physicians, dentists, and nurses, and to nearly all the institutions concerned with human ills. These various groups giving medical service must suffer or profit together from the workings of such legislation. It is impossible to separate their fates, even in discussion, and certainly not in programs of action.

Since Bismarck compelled the enactment of the first compulsory social insurance laws in 1883, similar laws have been enacted in practically every European nation, in Japan, and in several South American countries, and are under favorable consideration in nearly all other countries, including Canada, Australia, and South Africa.

The International Labor Conference, which includes every nation belonging to the League of Nations, at its meeting in 1927, adopted an agreement binding all members to introduce compulsory sickness insurance as soon as possible.

While much is made of the distinction between *"compulsory"* and *"voluntary"* systems, the difference in degree is so slight that it is hard to draw the line between them, especially as the voluntary systems are constantly adding compulsory features.

In the United States, workmen's compensation laws have already given us a system of compulsory accident insurance in all but four states, while a constantly increasing number of states are extending these laws to cover "occupational diseases." Many features of compulsory insurance treatment have also been included in recent legislation for veterans. All of these measures affect the practice of dentistry as well as that of medicine.

It is to obtain the information that will help all groups of the medical profession to cope with the threat of state medicine that the Committee on the Study of Dental Practice of the American Dental Association is conducting a study of all phases of sickness insurance in Europe and America. As fast as the results of that study are available they will be placed before the members of the American Dental Association, and will be available at any time in the future when such legislative proposals are under consideration.

How French Dentists Met the Insurance Question: France is the latest great nation to adopt an extensive system of compulsory health insurance involving all branches of the medical profession. This law went into effect October 1, 1930, but it had long been under consideration.

When Alsace and Lorraine returned to France they brought back the German system of health insurance. In spite of the admitted defects of the German system there was a demand that health insurance be now extended to all of France. The first law passed in 1928, being largely copied from the German scheme was so full of defects that it raised a storm of protest, particularly from the medical professions.

When the government suspended its operation this gave an opportunity for a complete rewriting. The physicians and dentists, as often under similar conditions, had been caught largely unprepared. But they now got busy in earnest and to excellent effect.

The physicians raised a fund of over one million francs (about $40,000), set about a thorough analysis of insurance, formulated their demands and adopted them at a great mass meeting and then carefully laid out a campaign, which they carried through to a successful conclusion, to secure these demands.

Since the dentists were included in the law from the beginning, they joined with the physicians in support of the latter's demands and then formulated their own program.

Such a fight calls for a strong professional association. The French dental profession is divided into stomatologists and dentists with different educational standards, which previously had made common effort difficult. How the emergency caused them to forget their differences is reflected in these words taken from a circular issued by the stomatologists.

"It is necessary for every practitioner thoroughly to realize that any mistakes made now will govern our destinies in the years to come. * * * It is of paramount importance at this moment that the individualistic spirit in medicine give way to the collective spirit, which alone will permit some defense against the collectivities that are confronting us."

There was a dentist and a physician who were members of the Chamber of Deputies. From the beginning each of these worked both within and without the Chamber to push the following proposals of the medical professions:

1. Complete freedom of choice of practitioner.
2. Legitimation of all professional associations entitled to deal with the insurance societies by the national associations of the profession.
3. Direct payment of all fees.

4. Professional representation on all administrative bodies.
5. Complete safeguarding of professional secrecy.
6. No lay control of professional activities.

Every one of these provisions was written into the law. The dental patient brings to his dentist a letter of introduction from his insurance society. The work is performed; the customary fee charged and paid; the dentist then endorses the work done upon the letter which the patient takes to this insurance society and collects the amount due him, which in most cases is only a part of the fee. For prosthetic work the insurance society must first endorse the estimate of the dentist as to the cost.

There are representatives of the medical profession not only on every administrative body, but even on the governing committees of the insurance societies.

Although the insurance societies had more than six million members, nearly all voters, the medical professions, purely by virtue of organization, superior knowledge of the situation, and a well planned campaign won a victory so complete that their German confreres have enviously congratulated them on escaping the evils of the German system. This victory was so complete that instead of the enactment of the law being followed by "doctors strikes" as in other countries, the insurance societies "struck" in many places and refused to sign the uniform contracts presented by the medical professions in accordance with the law.

It may have been a trifle too complete a victory since the insurance societies are now beseeching the politicians to amend the law to take away some of the advantages gained by the physicians and the dentists. Whatever may be the outcome of this prospective fight, the medical professions will, at least, for the first time have the advantage which the societies have had under every other system, in that they will be in possession of the disputed territory and know exactly how to battle for their professional privileges.

How Insurance Affects German Dentists: Germany was the first nation to install health insurance. Now after almost half a century of experience it is possible to pass judgment on nearly all its results.

The fact that German dentistry was from the beginning divided among two classes of practitioners has deeply influenced the relations of both insurance and dentistry. The *Zahnärzten* are physicians who have specialized in dentistry. Alongside of this class there grew up a constantly increasing number of dental technicians. As prosthetic dentistry grew in importance as compared with dental surgery, these came to take over more and more of the dental field, especially among the insured.

When insurance was established, there was practically no prosthetic dentistry, at least among the working class. There were thus three lines of progressive increase; first, number of insured; second, relative importance of prosthetic dentistry; and third, largely as a result of the other two, in the number of dental technicians and consequent scope of their work.

Insurance societies seek the cheapest service that will be satisfactory to their members. In the beginning, at least, the dental technicians charged less than the dental surgeons. In many cases insurance physicians prescribed and directed the work of dental technicians.

Soon the technicians began to develop their own special professional skill, standards, educational institutions, and organizations. At the present time they have obtained official recognition for the graduates of their dental institutions, which they claim are modeled on the dental schools of the United States. They have assumed the name of "dentists" in spite of strenuous protest from the *Zahnärzten*. They now largely dominate the great insurance practice.

Unfortunately the insurance societies were able to play upon the antagonism of these two branches and thereby drive the rewards for insurance dental work down almost to the starvation point. At first the *Zahnärzten* were not so greatly affected because dentistry was still a luxury profession; but when insurance brought so large a section of the population, hitherto almost without dental care, within its scope, it dominated dental service.

When the two divisions of the dental profession tried to cooperate against the insurance societies, the insurance men established great clinics. It is complained that in many cases excessive sums were invested in the building and equipment of such clinics largely for advertising purposes. These clinics were staffed by whichever section of the profession could be hired most cheaply. Usually both branches were utilized, but the number of "dentists" so employed was much the larger.

The political and social power of the societies and the weakness and unpreparedness of dental organizations prevented the profession from maintaining control of clinics. These are, therefore, operated almost entirely in the interest of the societies with a disregard for prefessional interests. Once established they did not confine themselves to insurance patients, but entered upon general practice on a strictly commercial basis. They even invaded the "luxury" practice and supplied private patients with expensive dentures of precious metals such as are forbidden in insurance practice. In short, the course of evolution, political conditions, weakness of preparation and divided organization have all combined to bring upon the German dental profession the very worst effects of the insurance system.

Next Annual Meeting, Hotel Syracuse, Syracuse, N. Y., June 1, 2, 3, 1931.

THE ANNUAL MEETING

This issue contains the first installment of the plans for the annual meeting of the Medical Society of the State of New York, which will be held in Syracuse, June 1-3, 1931.

The scientific program is the feature which will appeal to most members of the Society, for no matter what other activities the Society may undertake, its great function is to teach and inspire its members to practice medicine according to the highest standards of the profession.

The technical exhibits are also of importance, for they consist of the tools which doctors use in the practice of their profession. It is the intention of the managers of our Journal to promote a friendly relation between our exhibitors and advertisers on the one hand, and the readers of our Journal, practically all of whom are members of the Society.

The next issue of the Journal will contain the annual reports of the officers and committeemen, which will form the basis for the discussions in the House of Delegates.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—No. 20

The Public Welfare Law has been in effect for two years. A survey of its efficiency in meeting the problems that it was intended to meet can now be made in the counties where it has been fully used. In these counties, it has shown its value in better care of the indigent and in meeting the financial burden of medical service by general taxation, hitherto largely carried by the medical profession.

During the year the President has had a chance to study the operation of the Welfare Law in several of the counties. The first observation is that wherever the law is working well, it is because of the cooperation of the county medical society and the County Welfare Commissioner in developing the principles of administration. To illustrate this I cannot do better than to tell the simple story of the methods used in one of the counties.

In Suffolk County there were many misunderstandings between the Welfare Commissioner, the hospitals, and the medical profession. In the beginning of the use of the law the social problems and the county's responsibility under the law were not well understood by the Commissioner. This is not surprising at all because there was no former experience to be used as a guide. The hospitals had not made a uniform ward rate for county cases. Some were charging less than they could afford to give the service for. They were not giving equal service of laboratory, *x*-ray, and other instruments of precision. The charges that could be made for medical service were being decided individually and it was not clear to the doctor what charges to make for any feature of medical work that could be reasonably standardized. Other details such as authorization for the hospitalization or the treatment of the patient at home were not understood.

The Suffolk County Medical Society through its Economic Committee undertook to bring about an understanding of the provisions of the law and a practical application of them as they affected each group interested in its administration. The Economic Committee called a luncheon meeting, at one of the hospitals of the county, of the President of the County Society, the Public Welfare Commissioner, and the superintendents of the five hospitals. The result of this first conference was to come to an agreement between the three interests,—the county, the hospitals, and the medical profession. At the close of the meeting the Commissioner expressed his appreciation of the friendly attitude of the medical profession and of the willingness of the hospitals to cooperate in the working out of the administration of the law in the county. He then added, "I wish that I could have had this help in the beginning. It would have prevented some difficult questions."

My second observation is that governmental interests are willing to be guided by the medical profession in the solution of problems involving the technical service of medicine.

At this meeting the hospital rate was made uniform at three dollars and fifty cents per day for county cases and there was a clear definition formulated of what was to be included in the rate,—one *x*-ray picture in fractures and routine urinalysis. If further service is needed, it is to be charged for after obtaining authorization of the Commissioner who agreed to accept the opinion of the attending physician that it was necessary.

Upon request of the committee, the Commissioner agreed that the doctor should be paid his usual office fee in the office or in hospital service and that the fee for calls should be the average of those prevailing in the county. This would mean in Suffolk County that two dollars would be paid in the office or a visit at the hospital and that three dollars would be paid for calls to the patient's residence. Emergency work was to be taken care of at the doctor's initiative and authorization obtained for further treatment within forty-eight hours from either the Welfare Commissioner or one of the local deputies.

A month later another luncheon meeting was held for the purpose of discussing any problems that might have arisen in the administration of the law and for the purpose of discussing fees for operations, obstetrics, and other technical services. An agreement was reached to become effective after adoption at the next regular meeting of the County Medical Society. Later I will report on the action of the County Society. Many minor details of administration were discussed in this meeting. It is not necessary to report them for information because they were peculiar to the county and would not apply to other counties.

I am endeavoring to discuss the general principles applicable to the successful administration of this law and which can be made use of in every county of the state. For example, authorization must be obtained from the Welfare Department as soon as convenient except that emergency cases shall be taken care of on the doctor's initiative until in reasonable time, he can obtain authorization. In a general way, it was agreed that a reasonable time was forty-eight hours. It is necessary for the doctor to have this authorization in order to be paid for his work. In the opinion of the Suffolk County Medical Society this is a proper regulation since it is concerned with public business and spending the taxpayers' money. Just because payment is made by the county gives no license to charge more than the average fees prevailing in the locality. The ethics of the medical administration of this law impose an obligation to play the game squarely.

If the Welfare Law is not functioning prop-

erly in any county I believe that it is fair to say that the medical profession should usually be blamed for it. The profession owes a duty to the public to cooperate with the Public Welfare Commissioner in making the law effective. In addition to its value as public policy it is of value also to the medical profession since it is solving one of the problems of medical care by compensating the doctor for professional service.

WILLIAM H. ROSS.

THE HEALTH COMMISSION BILL

Two inapplicable motives have been ascribed by high officials to physicians who have opposed the County Health Unit feature of the State Health Commission's bill. One was that local health officers would lose their positions if the County plan were adopted.

The second was stated in a news item in the New York *Times* of Thursday, April 9, 1931, page 14, which says:

"Disregarding urgent recommendations of Governor Roosevelt, the Republican majority in the Assembly passed today a bill from which the sections held vital by the Governor and the special committee had been removed. It is expected that the Senate will pass the bill in the same form.

"The commission, headed by Dr. Livingston Ferrand, president of Cornell University, had urged the setting up of county health units as an essential feature of the twenty-year program.

"The Governor, in a special message, said he was aware that opposition to this portion of the measure was being evinced by local politicians, who feared a loss of minor patronage, and demanded that the health unit feature be retained.

"The bill, as it went through the Lower House, however, ignored the health unit program entirely.

"It appropriated $750,000 for three new tuberculosis hospitals, a division of cancer control in the State Health Department, and made some other general changes in the health regulations."

Local health officers, who constitute over twenty per cent of physicians practising outside of the larger cities, know the value of local home rule by the township, village, and small city. The local municipality is the natural unit to administer ordinary contagious disease control, and also for local sanitation, which is another name for civic housekeeping. The local health officers believe that there should be a county health department to assist the local health officers in the larger emergencies, and to do the larger forms of health department activities such as milk control and child welfare work.

The local health officers wish the State system of public health work to be organized like that in the army, in which the company is the smallest administrative unit and the captain is responsible for health and sanitation within his own area. But the battalion major is equally responsible for the area of his four companies, and the colonel for all his battalions. The line of command goes down to the company commander in all health matters pertaining to the company. This is what was intended by the local health officers when they were accused of being afraid of losing their jobs and political patronage.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Cause of Cancer: This Journal of April, 1906 contains an article on Cancer by Dr. Samuel Lloyd in which he states that he is convinced that cancer is communicable. He says:

"I am absolutely convinced of this fact myself, and have for years been watching the collection of data from various sources proving it.

"First and most convincing is the increasing ratio of cancer to the population, as shown by the health statistics of different countries, our own included. Second, it has been shown that cancer is more common in thickly populated sections, where the people are crowded together, the air is vitiated, and cleanliness is less regarded than with the better housed and fed."

Dr. Lloyd then describes five cases of which the following is typical:

"Woman died of cancer of the breast. Two years later I operated upon the sister, who had nursed her, for cancer of the stomach. There were no previous cases of cancer in the family."

The doctor continues his argument by referring to metastases in a way which is entirely accepted today:

"Auto-infection with cancer is now a well-established fact, and surgeons generally are adopting every possible precaution to avoid injuring any of the cancerous tissue during the course of an operation, in order to avoid spreading any of the cancer cells in the operative field." This practice is generally observed today.

MEDICAL PROGRESS

Sleep and Its Disorders in Childhood.—Hector Charles Cameron discusses three factors which may be concerned in producing sleeplessness in young infants, namely, pain or discomfort, inherited or constitutional neuropathy, and faulty management. In a few cases the unrest is caused by persistent pain, as in syphilitic periostitis, the subperiosteal hemorrhages of scurvy, uric acid calculi, and otitis media. The pains of dyspepsia and aerophagy are more common causes. Brought to the breast sleepless, crying, and excited, the child gulps, strains, and chokes, and thus secures from the breast a minimum of milk and a maximum of air. The consequent distention of the stomach is painful. Nasal obstruction from nasal catarrh is a frequent cause of wakefulness. A tampon of cotton-wool, which allows a few drops of adrenaline solution (1:5000) to flow backward through the nostrils before the child is put to the breast, may permit nasal breathing and suction, and thereby prevent aerophagy and hunger. Few babies suffer from inherited neuropathy. Most infants who are sleepless and who cry constantly without any specific pain and discomfort do so because the management is at fault. It is through the mother or the nurse that we must work to get our effects. No infant lies quiet in the arms of a woman who is herself in a state of nervous tension. Insomnia and constant crying may become persistent when the mother grows agitated and worried by her failure to dominate the opposition of the child. The best place for such an infant may be up against the mother's back, against a warm, comfortable part of her body which takes no part in the expression of her emotions, when the searchlight of eyes and face is directed away from the child, and when her hands are free to busy themselves with occupations which divert her thoughts from the child. Chloral is the most effective hypnotic in infancy and may be used until the rhythm of sleep is restored. Many nervous older children will sleep only in the presence of the mother. The persistent hailing of the mother, as soon as the light is turned out and the child left alone, is caused by the effect upon the child of the ill-concealed agitation in the mother. To urge a child to go to sleep is only to call attention to his own importance in the matter. On the other hand, to speak before a child of his remarkable capacity for immediate and sound sleep, to call attention to his improvement is to provide helpful management. Cameron directs attention to the importance of metabolic disturbances as a cause of insomnia in nervous children. In children, starvation, pyrexia, exertion, and emotional excitement tend more readily than in adults to exhaust the reserve of carbohydrate, leading to hypoglycemia and ketonemia, which in turn are likely to result in sleeplessness, night terrors, or enuresis. A higher percentage of sugar and a somewhat lower percentage of fat are the chief needs of the nervous child.—*Journal of the Canadian Medical Association,* February, 1931, xxiv, 2.

Clinical Researches on Chlorophyll.—Lorenzi Angelo describes in the *Riforma Medica* of January 19, 1931, his researches on the action of chlorophyll in individuals with normal and with excessive blood pressure. His experiments were carried out on 50 subjects, of whom 10 were normal, 17 suffered with hypertension and poor general condition requiring hospitalization, and 23 had hypertension but were able to live a normal life. In all cases chlorophyll extract was used in aqueous solution in doses of 0.80 to 1.50 gm. per day, no other medication being administered. The chlorophyll was well tolerated even in strong dosage over months of time. In the group of normal individuals no particular results were seen in the blood pressure. In the second group a constant and appreciable lowering of blood pressure began on the 5th to the 8th day, the systolic pressure falling 30 to 60 mm. Hg and the diastolic 20 to 30 mm. In the third group results were similar, but were not observed until the 15th day. The results in this group assume an importance, since these individuals were continuing their regular habits and the change could not be charged to hospital care. At the same time that the blood pressure was coming down the general condition of the subjects improved. The effect of the chlorophyll was to cause a vascular dilatation, to stimulate arterial contractility, to improve the peripheral circulation and thus to relieve the work of the heart. In some cases the results continued for 1½ months after the treatment was stopped, while in others the blood pressure went back to its old figure again in 10 days. Two hypotheses are possible: either that the chlorophyll removes the causes that obstruct the circulation, or that it diminishes the quantity of exciting substances in the circulation. That the first of these is true was definitely established by the experiments. As regards the second, one can only suppose that the improvement in the peripheral circulation favors the elimination of

toxic substances, and hence diminishes the effect of these upon the circulation. In either case there would be a certain parallelism with the action of digitalis.

Symptomless Acute Mastoiditis.—N. Asherson emphasizes the importance of recognizing the fact that not all cases of acute suppurative mastoiditis are associated with symptoms. It is possible that an intracranial extension such as a perisinus abscess may exist without giving rise to subjective symptoms. It is generally recognized that one of the most reliable signs of acute mastoiditis is a sagging or bulging of the posterior superior wall of the osseous meatus where it abuts on the tympanic membrane. What is not widely accepted is the important fact that this bulging or sagging may be the only sign or symptom indicating the presence of a suppurative mastoiditis, or even an intracranial collection of pus. Its detection depends on routine otoscopic examination of all acute ear conditions, after the meatus has been thoroughly cleansed of all discharge by syringing and mopping. The best view of the tympanic membrane is obtainable with the electric otoscope, the only instrument which makes possible the adequate examination of the ear in an infant or refractory child. A second important physical sign for opening the mastoid process is the rapid refilling of the meatus with pus after it has been thoroughly cleansed. If, in addition, the radiogram reveals a sclerotic process, that is, one devoid of cells, it is obvious that the collection of pus must be either perisinus, extradural, or cerebral. It could not arise from non-existent cells in the mastoid, and if it arose merely from the antrum the meatus would not refill so rapidly. If a patient with a running ear has any symptoms suggestive of dural involvement, as, for instance, vomiting, this symptom must be regarded seriously. —*The Lancet,* February 14, 1931, ccxx, 5607.

Autogenous Puerperal Infection.—J. Voron and A. Brocher say there can be no doubt of the existence of cases of puerperal infection in which it is impossible to incriminate any septic contamination from an outside source. The source of the microorganisms is on or within the body of the patient herself, previous to her accouchement, in genital or extragenital foci. When it is within the genital zone, the patient may be a carrier, either healthy or diseased. There is no infallible test by which the existence of such forms of infection can be demonstrated: the conviction that this is the case is reached only by a careful analysis of the facts, since numerous causes of heterogenous infection still elude detection. The increased prevalence of puerperal infections during endemics of grip argues for an autogenous origin. As a rule the evolution of such an infection is due to a weakening of the general and local defenses of the organisms rather than to the virulence of the responsible bacteria. Every woman carries in her genital tract microorganisms which live there in the state of epiphytes. Clinical arguments for the existence of an autogenous infection are found in the persistence of the puerperal infection; its appearance in the absence of any external contact in a rigorously clean environment, and its greater frequency in the winter months. Predisposing causes are (1) exaggerated length of time in labor, carrying with it the element of "bruising"; (2) obstetrical interventions which injure the tissues, reduce their vitality, and diminish their resistance to microbes; (3) the carrying of vaginal flora into the uterus by even aseptic manual delivery, and (4) retention of coagula, lochia, or ovular debris, which offer an admirable milieu for culture. Autogenous infections are generally mild, with few grave cases. Up to the present time, attempts at prophylaxis have borne little fruit. Measures in the right direction are (1) care of the health during pregnancy, (2) reduction of fatigue to a minimum during labor (3) suitable therapy to avoid obstetrical shock, (4) the overcoming of anergy, as by proteinotherapy or nucleinate of sodium, and (5) attempts at immunization, especially vaccinotherapy, which has given encouraging results. —*Journal de Médecine de Lyon,* February 5, 1931.

The Incision for Appendicectomy.—A. J. Southam, writing in the *British Medical Journal,* February 14, 1931, i, 3658, calls attention to the danger of injury to the nerves of the abdominal wall with the McBurney muscle-splitting incision for appendicectomy. He recalls that, in 1924, he pointed out that a right inguinal hernia sometimes followed the use of the gridiron incision, and since that time he has encountered several additional cases showing this complication. He thinks it doubtful if the connection between the appendix operation and the subsequent appearance of the hernia is often recognized. The hernia probably results from some injury inflicted on the ilio-inguinal nerve during the operation for the removal of the appendix. It is at the point where the nerve lies external to the anterior superior iliac spine that it is liable to be damaged. The nerve lesion results in paralysis of the muscles and the conjoined tendon around the internal abdominal ring and in the subsequent appearance of inguinal hernia. In three recent cases in which a second operation was undertaken for the radical cure of hernia following the muscle-splitting incision, Southam excised a portion of the ilio-inguinal

nerve and submitted it to pathological examination. All three nerves showed partial degeneration, varying in degree. The paramedian incision has the advantage that it can be extended to any length. In many cases, however, it will be found at some distance from the site of infection and will necessitate very careful packing off to avoid the risk of soiling the general peritoneal cavity. In typical cases of acute appendicitis localized in the right iliac fossa and in young patients, Battle's pararectal incision with inward displacement of the rectus muscle gives adequate exposure, and as the nerves can be seen and readily avoided it rarely leads to any subsequent weakness of the abdominal wall.

Results of Roentgen Disinfection of Diphtheria Carriers.—Rudolf Wahl gives an account in the *Deutscher medizinische Wochenschrift* of February 13, 1931, of the methods adopted in Magdeburg in 1929 to rid diphtheria carriers of bacilli. Everyone in the Magdeburg-Sudenburg Hospital—infants, children, or adults—who was known to be a carrier was subjected to irradiation of nose or throat or both. If there were carriers in the families of these persons, 3 smears were made from nose or throat within 8-14 days, and if all were positive, the carrier was advised to undergo irradiation. Naturally some difficulty was encountered in overcoming prejudices, even physicians of the city being skeptical in some cases. The results were of especial importance, since in many cases the carriers had given positive cultures for weeks or months. Only in exceptional cases were more than 3 irradiations given. About 5 or 6 days after an irradiation a control smear was made and examined bacteriologically. The interval allowed between irradiations was 2 to 3 weeks. At the first, or principal, irradiation the largest dosage was given, amounting to 30 per cent of the skin erythema dose and to not much less on the tonsils, for the layer of tissue that the rays must penetrate is not very thick. In infants one-half this dose was given. When a second or third treatment was necessary, 10 per cent of the erythema dose measured on the skin was given. In the year just ended 136 carriers were irradiated, of whom 133 carried the diphtheria organism, 1 streptococcus, and 2 meningococcus. Of this number 96, including the streptococcus and meningococcus carriers, were already negative after the first irradiation. Another 27 became negative after the second treatment, and in only 3 was a third treatment necessary. A carrier was considered diphtheria-negative if he showed 3 negative smears within 3 weeks after irradiation. It seems justifiable to believe that the use of this procedure is largely responsible for the decreased number of diphtheria cases in Magdeburg as compared with the period before 1923. In view of the small dosage given, it seems improbable that the rays act directly upon the bacilli to kill them, Smears made immediately after irradiation are always strongly positive, and remain so for several days. Rather is it probable that a nonspecific resistance is developed in the bodily tissues.

Nonspecific Protein Therapy in Nose, Throat, and Ear Affections.—After a brief review of foreign protein therapy in general, Joseph C. Beck states that he has employed this treatment in various pathological processes about the nose, throat, and ear. The conditions treated were the following: Otitis externa, eczematoid, follicular, or furunculous; chronic sinusitis, suppurative and nonsuppurative; postoperative sinusitis, after both conservative and more radical operations; atrophic rhinitis; chronic tonsillopharyngitis, with or without acute intercurrent attacks; chronic laryngotracheitis, especially suppurative; bronchiectasis, and borderline cases such as chronic suppurative disease of the salivary duct or any of the salivary glands, and fistulæ about the head and neck. He concludes that the results of foreign protein therapy, in his hands at least, have not been encouraging. While anaphylactic shock has not occurred in his series its possibility should be borne in mind and a careful history should be taken, especially as to the previous use of biological sera, and this particularly in children. Protein injection should not be given unless adrenalin is at hand for emergency use. Clearly indicated surgery was not permitted to be superseded by nonspecific protein therapy and when the latter was employed in systemic contraindication to surgical intervention, its use was not attended by any noteworthy benefit. The chill that has been supposed to be of prime importance in foreign protein therapy was rarely observed in this series of cases. Other therapeutic measures, such as specific sera, vaccines, allergins, chemicals, physical agents, diet, and endocrines, also possess definite nonspecific protein effects as adjuvants. Beck thinks that pure certified milk, free from bacteria, not boiled, is preferable to boiled milk containing bacteria, since the bacteria supply additional proteins and the dosage cannot be definitely controlled. He expresses regret that too many men employ nonspecific protein therapy on the advice and information of commercial salesmen of the various milk, bacterial, and other products, without the necessary laboratory and scientific medical control. This can only lead to the disrepute of the treatment.—*Laryngoscope,* February, 1931, xli, 2.

Treatment of Pneumonia by Intravenous Injections of Sodium Salicylate.—Couvy and Popoff, writing in the *Bulletin de l'Académie de Médecine* of February 3, 1931, give an account of their recent work in the native hospital of Dakar (Senegal), where during the last 2 years they have treated 114 cases of pneumonia in

African Negroes with intravenous injections of sodium salicylate. Of these, 46 were very grave cases, with delirium and cardiac insufficiency, 43 exhibited considerable gravity with symptoms of icterus, and 25 were average cases with favorable prognosis. When to these are added 26 cases on which the authors had made a previous report, the total number of cases treated is 140, of which only 7 (5 per cent) terminated fatally. The patients had been admitted in every stage of pneumonia from the second to the tenth day. The technique consisted in the intravenous injection of 30 c.c. of a 1:30 solution of sodium salicylate once or twice daily, according to the general condition of the patient. Its action was astonishingly rapid, producing prompt improvement in the adynamia, the toxinfectious phenomena, and the cardiac condition. The dry tongue became moist, the patients, detoxicated, began to feel a sense of well being, and were soon out of danger. The temperature usually dropped by crisis, in either one or two stages. Occasionally a fall of temperature after 1 or 2 days of treatment was followed in 18 to 24 hours by a fresh rise, with a final drop after 1 to 3 days at most. Treatment is stopped after the temperature falls, but is resumed if fever returns. In cases of average severity resolution is plainly hastened, and if the patient has treatment during the first 3 or 4 days definite apyrexia is established by the 6th, and sometimes even by the 4th day. In no case has injection been followed by any untoward symptom, such as induration or signs of toxicity. The maximum dosage reached was 11 grams in 6 days, in 11 inoculations. Moeller in the Belgian Congo has had good results with sodium salicylate administered by mouth, reserving the intravenous method for very severe cases.

Asepsis: A Possible Interference with the Physiology of Repair.—Herbert L. Johnson contends that, in view of the traumatic possibilities of the environment of primitive man, nature must have expected infection and contamination in every case of trauma. There is some evidence that bacterial toxins, irritating chemicals, and foreign bodies are depended upon to stimulate the serosa to a vigorous defense reaction for the purpose of neutralizing the damaging effect of their presence. The first stage of repair is chiefly concerned with the production of a plastic exudate rich in fibrin, leucocytes, and a host of unknown factors. Fibrin plays the major rôle in the mechanism of repair. By its close adhesion to inflamed surfaces it delays absorption. The diffusion of an inflammatory process in the peritoneum is dependent on or follows a deficiency of fibrin. It is obvious that any process which interferes with or prevents fibrin formation is a dangerous one. During the stage of structural repair the fibrous strands deposited in the process of defense reaction act as guides to the growth of new tissue and serve to house the elements of defense within their meshes, forming thereby a barrier against infection. The light aseptic trauma inflicted upon the serosa in the average "clean case" is not in itself sufficient to excite the production of a heavy plastic exudate. In consequence moderately abraded surfaces lie in contact and heal together, giving rise to the most damaging type of adhesions. The relinquishment of any small part of the advantages of asepsis and antisepsis is inadvisable. It is suggested, however, that we should seek a harmless substitute for the excitor effects of bacterial toxins, chemical irritants, etc., in order that we may more fully conform to the scheme of normal repair.—*New England Journal of Medicine*, March 12, 1931, cciv, 11.

Adrenalin in the Treatment of Contraction Ring, with Note of the Action of Adrenalin upon Tubal Contractions.—M. Pierce Rucker recalls that in an earlier communication he showed that adrenalin administered in 5 minim-doses of 1-1000 solution, hypodermically, caused a cessation of labor pains for a period of from nine to thirty minutes in 16 out of 20 cases. In 1927 he read a paper on the "Treatment of Contraction Ring Dystocia with Adrenalin." Later in the same year Bourne and Burn of London did practically the same work with adrenalin, and recently they have stated that such work has never been done before. Evidently they failed to consult the American literature. The action of adrenalin on the uterine musculature makes this drug of practical use in cases of advanced contraction ring, causing the disappearance of the obstruction for a sufficiently long time to permit of version or forceps extraction. In cases of contraction ring of moderate degree, the cause of prolonged labor is often unrecognized. In such cases investigation will frequently reveal a constricting band of uterine muscle about the baby's neck. By injecting subcutaneously 5 minims of 1-1000 adrenalin solution forceps extraction becomes surprisingly easy. Rucker reports a case of threatened abortion in which the use of adrenalin was apparently effective in stopping uterine contractions and making it possible to carry the patient to term. He suggests that its use in these cases is logical. He also records observations made with the Rubin apparatus for insufflating the fallopian tubes. After the initial spasm has passed off and the flow of gas has become constant, an injection of adrenalin causes a relaxation of the musculature of the tube and often a slowing of its rate of contraction. Pituitary extract, on the other hand, shows an increase in the tone and the rhythm of the contraction.—*Southern Medical Journal*, March 1931, xxiv, 3.

LEGAL

RETAINED FOREIGN BODY
COURT OF APPEALS HOLDS SURGEON BLAMELESS

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

In a case in the writer's office, our Court of Appeals recently handed down a decision of great importance not only to the individual doctor concerned in the case, but to the entire medical profession as well. The charge against the physician was that he had negligently left a foreign body in the abdomen of his patient. The decision of the Court of Appeals sustained the Appellate Division, which Court had by a divided vote decided in favor of the physician. In order to understand the force of the decision it is necessary to state the facts somewhat in detail.

The defendant physician was called in to see a married woman about thirty-eight years of age. She gave him a history of having sharp shooting pains in the lower right abdomen and complained also of a pain at the pit of the stomach that had shifted from the right lower abdomen. She told the physician that she had these sharp little pains continually, and then a sharp sudden agonizing pain. There was some slight flowing. The patient had missed one period. An examination of her abdomen disclosed that it was very sore, tender and rigid over the right lower section. The doctor made a diagnosis of a probable extrauterine pregnancy with a possible appendicitis, and advised immediate operation. To this the patient and her husband consented and she was immediately taken to the hospital, the doctor having telephoned the hospital and told the authorities that he was going to operate immediately on an emergency case.

After the physician had scrubbed up, and the patient had been prepared for operation and anesthetized, the defendant proceeded to operate. He made an incision to the right of the umbilicus, extending downward to the pubis, and went through the abdominal wall. Upon exposing the peritoneum, he found the lining of the abdominal wall was inflated with blood shooting through it. He then opened the peritoneum and retractors were inserted to spread the wound open. When these were inserted, the blood shot out in great quantities in the peritoneal cavity. The defendant testified it was necessary to work fast in order to stop the bleeding. The intestines were distended, so that in order to push them to one side and work down through it was necessary for the doctor to use pack-offs to hold the intestines back. The pack-offs used in this operation were large pack-offs. The pack-offs were handed to the operating surgeon by a sterile nurse, and the doctor testified that he relied upon the hospital nurses to hand him the correct pack-offs. The defendant testified on this point:

"Q. And you rely upon the hospital nurses to hand you those and hand you the correct ones? A. Yes, sir. She hands it to us like that, supposed to be moistened, so that we can put one of these in and leave it.

"Q. In where? A. In the abdomen until we are through our work, but where we have got blood seeping down from the upper abdomen into the region where we are operating we have to change these frequently, because they hold the blood back for a little while, then it seeps through and obscures our field again. Then we have to take this out and put in another one. So we use these both for sponges and for pack-offs. Now, say we use this—this is an operating room habit

---

"Q. Usual, proper and approved method? A. To my mind.* * *

"A. (Continued) We put this in. The first thing my assistant does or I do when we get that we snap that artery clamp on to the sheet again, as I did before. We snap that snap into the artery clamp. Now, no matter where that is that can't get away from us, even that big thing like that. We are afraid of even these things there. Every one of these we use is snapped to the artery clamp like that. The other piece of gauze is sewed to the bottom of the bag. If you pull that out you will see it.

"Q. The other piece of gauze, referring to Defendant's Exhibit 2? A. Yes, the continuous strip sponge. Now, that is snapped there. That is the purpose of the snap is to snap it on to something so you have got it. Now, these are all we use in the course of that operation, actually use. When we come out they hang over the edge of the table like that. When we get through with them, throw them on the floor or in a pan. That looks big now. When it is wet it is quite small. Now, when these go into the abdomen, in spite of this hook here we count them. That is, if I put one in the abdomen, I say one in, in my mind, and I am keeping track of these. When I take the second one and put that in on top of it, two in. I take one out, two in, one out, one in. That is running through your mind sub-consciously all the time. Sometimes we say it to each other, my assistant and I. Now, we take these, put them in, snap them on like that. When

we put them in leave them in there until their purpose was finished, take them out, throw them on the floor or in a pan Sometimes after we take them out and they are on the floor we have to unsnap that in order to get them out of the way Now, we did that I went down in ——

"Q You are referring to the large pack off which is Defendant's Exhibit 1? A Yes Now, we used these under those precautions Then I removed the tube That in itself stops the hemorrhage

"Q You mean the Fallopian tube A Yes

"Q That is, you cut that right out? A You tie off the blood supply coming to the tube on both ends That naturally ties off the vessels coming to the tube and the bleeding ceases, but of course the tube is destroyed and has to come out

"Q And it did come out in this case A It did come out in this case Now we get these out Then we are ready

"Q When you say these, you mean Defendant's Exhibit 1? A Yes I took out her appendix, which was perfectly normal, on the way out I could do it very quickly, simply to prevent her having appendicitis That was in the way and we grabbed it You can do that in a minute Then we came out We got ready to close the abdomen Then I put my hand in the abdomen and felt all around to see if there was anything left in there You can imagine a clamp like that might slip down in there * * *

"A (Continued) A clamp like that might slip down in there Any number of things can get in there so we feel around to see if we have left anything in there I do that myself

"Q Did you do that in this case? A Yes not only that, I had my assistant do it, feel around in there to see if there is anything

"Q Did your assistant do it in this case? A Yes

"Q Who was your assistant in this case? A Dr. X Then we are ready to close the abdomen I turn and ask the nurse who is in charge of the operation room, how is your count? That means, how is the count of the gauze and all those things Before closing the abdomen I have her assurance and I had in this case that the count was correct * * *

'A (Continued) She tells me the count is correct then I go ahead and close the abdomen which I did in this case"

The doctor continued to see the patient once or twice a day The patient remained in the hospital about three weeks and made what appeared to the doctor to be an uneventful recovery There was nothing about her condition that indicated to the doctor that any foreign body had been left in the abdomen

About two months after the patient left the hospital she called the defendant to her home complaining of severe abdominal pain On examination the defendant found distension of the large intestine He advised an enema and when this had been given to the patient she felt relieved Two months thereafter she had a similar attack which was also relieved by an enema There were no symptoms indicating the presence of a foreign body

About nine months after the operation x-ray pictures were taken by another physician of the plaintiff The defendant upon examining the pictures found that they disclosed the presence of a buckle with gauze attached Upon ascertaining this fact, the defendant immediately telephoned to the woman's husband and told him that it was necessary to reoperate because of adhesions in the pelvis and also by reason of the presence of the foreign body The woman at that time was pregnant, and the doctor told the husband he could use his own judgment as to whether the patient should be told either about the adhesions or the foreign body The defendant reoperated the patient, and his findings upon that operation were testified by him to be as follows

"Q * * * Please tell the Court and jury just what you did in that operation, what you found and so forth A I went in The patient was brought in exactly the same, put under ether and we went through the same preparation and I made an incision through the old scar I made the other time This takes out all the scar tissue and lets fresh tissue in again It makes the new scar about half an inch longer than the old one I reopened the abdomen exactly as I did before The first thing I did was look to the pelvis down back of the uterus There I found what we call a sigmoid, that is the large intestine just above the rectum down back of the uterus was pulled over the right and stuck adherent to the place from where this tube had been taken off The tube was adherent too when I took it out

"Q You mean the Fallopian tube? A Yes I found it was stuck there Now, that pulled the intestine over making a kink like that I separated that adhesion It was so dense I had to take a knife and cut it, cut a piece off the back of the uterus, let this large intestine get away from the back of the uterus and sewed up the place I took off After doing that I looked over the region where we had removed her appendix This time we had no hurry or anything We could take our time I found that all right Then I went after the buckle and I pulled out the omentum That omentum is the sheet I told you about which in her case was very thick I pulled that out and I looked and could feel something in the middle of that I just separated where that had folded over and kind of adhered to this and I found some gauze

'Q (Handing witness Plaintiff's Exhibit 4) Using that, describe as near as you can what you

found. A. On opening up this omentum, this big sheet, I found wrapped up in it, the omentum all around it a pack-off like that, lying just like that, with the snap hanging out about that distance and extending downward and to the right. There was the pack-off like that. I separated the omentum around it, pulled on it and kept separating the omentum from the side and took it out. It looked just about like that except, as I say, it had been sterilized and discolored a little bit. Then I separated all these light adhesions on the omentum, spread the omentum all out. There were two little loops of small intestine adherent to the omentum. I separated those, restored things just as they should be, straightened out the omentum, tucked it down into the pelvis and again closed the abdomen.

"Q. Now, Doctor, referring again to Plaintiff's Exhibit 4, which you have in your hand, as being nearly identical with that which you removed on the second operation, will you tell the court and jury whether or not in your first operation you were using any pack-offs like that? A. No, the only pack-offs I used were like that.

"Q. In other words, the small pack-off was not of the type you were using or calling for? A. No.

"Q. Now, the fact undoubtedly is, as we have frankly admitted, that the foreign body was left in her abdomen? A. Yes. * * *

"Q. Did you at any time during the first operation see any pack-off of the type of Plaintiff's Exhibit 4? A. No.

"Q. Did you knowingly insert any pack-off of that type? A. I did not.

"Q. Now, will you tell the court and jury from your knowledge of the use of these pack-offs whether or not it would be possible for the small pack-off, Plaintiff's Exhibit 4, to have been rolled in the other pack-off and handed to you and thus inserted? * * *

"The Court: I think it is apparent one could be rolled within the other. * * *

"Q. What did the fact that this small pack-off, Plaintiff's Exhibit 4, was rolled up at the time you removed it (the second operation) what did that fact indicate? * * *

"A. I found that pack-off rolled up. That indicated that the pack-off had never been used, otherwise it would have been unrolled. I found it rolled up like that.

"Q. In other words, no pack-offs are ever put in unless they are unrolled? A. No.

"Q. When you found this small pack-off in this second operation was it encysted? A. No, not what you call encysted.

"Q. What was its condition, then? A. It was surrounded by omentum. Encysted implies that there has been a lot of inflammatory reaction around it so as to produce a sac around it.

"Q. There was no sac? A. No sac.

"Q. What did that indicate? A. It indicated that the pack-off, in itself, had caused very little irritation.

"By the Court:

"Q. Was the buckle encysted, Doctor? A. No, sir."

The doctor also testified that he did not employ the nurses and had nothing to do with their employment. An expert physician was called by the defendant who testified on a hypothetical statement of facts that the defendant followed proper practice. This physician also testified that the defendant was absolutely correct in not making an extended search into the plaintiff's abdomen, since to do so might have caused a paralysis of the intestines and possible death.

The Court submitted the issues to the jury. The jury found in favor of the plaintiff. The case was appealed by the defendant to the Appellate Division, where the judgment of Trial Term was reversed and a new trial granted so as to give the plaintiff's attorney an opportunity to produce further proof. In reversing, the Court said:

"Plaintiff's theory was that the leaving of the pack-off in the abdomen made the lack of skill and want of care so obvious that expert testimony was unnecessary. But, defendant called an expert who said that proper and approved methods were used in the operation, and thus inferentially that there was no negligence. He stated that it would have been unwise for defendant to have made a more extensive search for foreign substances in the abdominal cavity at the close of the operation, and might have caused paralysis of the intestines; also that it was proper and customary for an operating surgeon to rely on the nurse's count of sponges, pack-offs and gauze placed in and removed from the incision. Plaintiff did not rebut defendant's medical evidence that proper and approved methods were used. The presence of the pack-off in the abdomen after the first operation standing by itself suggested that proper care had not been used, and required defendant to offer proof in explanation. But when defendant's expert witness stated that proper and approved methods were used in the operation, the possible inference of negligence because the pack-off had been left in the abdomen was destroyed. * * *

"This defendant was not chargeable with the negligence, if any, of the nurses employed by the hospital. (Baker v. Wentworth, 155 Mass. 338.)"

The plaintiff's attorney, however, did not submit any additional proof on the second trial and hence the complaint was dismissed. The plaintiff thereupon appealed to the Appellate Division, where the ruling of the Trial Court dismissing the complaint was affirmed. Inasmuch, however, as two of the Justices in the Appellate Division dissented, the plaintiff was permitted to carry the case to the Court of Appeals. The Court of Appeals unanimously affirmed the action of the

courts below and exonerated the physician from any liability under the facts disclosed by the record. No opinion was written by the Court of Appeals.

We have set forth the evidence in considerable detail in this editorial, since a knowledge of all the facts is necessary to a proper appreciation of the decision. The decision is an extremely important one bearing the stamp of approval of our highest Court, and we feel sure that it will be received by the medical profession with great interest.

ALLEGED WRONG DIAGNOSIS OF STOMACH AILMENT

The plaintiff in this case was referred to the defendant doctor, who specialized in radiography and X-ray therapy, by another physician, in order that a proper diagnosis might be made of the cause of annoyance from which this man suffered immediately after eating.

The doctor gave him a 14 ounce drink of barium meal mixed with water, and stripped him to the waist, placing him under a fluoroscope in order to observe the functioning of his stomach for three minutes. After waiting a short time he then took a series of six x-ray pictures of the man's stomach from various angles.

The patient returned six hours later and another picture was taken, and on each of three succeeding days additional pictures were taken. With all this data before him the defendant doctor sent the following report to the physician who had referred the patient to him:

"Findings on examination: The esophagus is normal. The stomach fish-hook in shape, no defects in curvatures, the lowest point, at the level of the crest. The duodenal cap slightly irregular on all films. Six hour examination—small gastric residue. The head of the barium column in the caecum. Twenty four hour examination—Moderate amount of barium in the colon. Forty eight hour examination—Colon empty of barium. Appendix—Not seen. Conclusion: Probably duodenal ulcer."

Nothing more was heard of the patient until some months later when he returned to the defendant's office and accused him of being wrong in his diagnosis of duodenal ulcer, when there was in fact nothing the matter with him except a stomach ache resulting from what he called a nervous stomach.

The plaintiff thereafter started suit in the Municipal Court of the City of New York based on malpractice and fraud. The plaintiff alleged that the defendant was negligent in improperly and carelessly diagnosing his condition as an ulcer and that by reason of such negligence he suffered great mental pain and anguish and was forced to incur considerable expense as a result thereof.

For three years after instituting the action plaintiff did nothing, and a motion was made on behalf of the defendant to dismiss the complaint for lack of prosecution. Said motion was granted, thereby terminating the matter in favor of the doctor without trial, which was a most fortunate outcome.

FAILURE TO BE PRESENT AT DELIVERY

In this case the defendant doctor was consulted by a woman who advised him that she was pregnant. The doctor examined her and arrangements were made for him to attend her during the remainder of her pregnancy and to deliver her of her child at the proper time. She continued to call at the doctor's office for about six months, all of which time she was progressing normally. At the last call the doctor directed her to notify him at the first sign of labor.

A few days later she entered a hospital, without the doctor's knowledge. The attending physician at this hospital called the doctor and informed him that the patient was in labor but not active and that there was very little dilation. The defendant doctor was at the moment busy with another patient and directed the attending physician to call him as soon as the woman became active. This call was received a few hours later and the doctor rushed to the hospital in an automobile. By the time he reached the hospital the woman had delivered herself of a normal child in a normal way and had suffered no ill effects as a result of the delivery. Neither the defendant doctor, nor the attending physician at the hospital were present at the child birth. The doctor examined the woman and found her condition to be excellent, and attended her daily until the time of her discharge from the hospital about two weeks later.

When the doctor saw her last he directed her to return to his office about six weeks later in order that he might make a further examination of her condition. This she failed to do.

A suit was instituted against the doctor in which it was charged that although the defendant had sufficient notice of the imminence of the plaintiff's labor, he failed to appear to attend her during her delivery, and for that reason she suffered great injury.

An answer and demand for bill of particulars was served on behalf of the defendant doctor. The plaintiff never complied with the demand for a bill of particulars and a few months after suit had been instituted, plaintiff's attorney consented to discontinue the action, thereby terminating the matter in favor of the doctor.

THE ANNUAL MEETING

PROGRAM OF THE SCIENTIFIC MEETING

The one hundred and twenty-fifth annual meeting of the Medical Society of the State of New York will be held in Syracuse Monday, Tuesday and Wednesday, June 1-3, 1931. The headquarters of the Society will be in the Hotel Syracuse; and the same hotel will house practically all the features of the meeting, including the House of Delegates, the scientific sessions and the technical exhibits.

Following the example that was adopted last year, the scientific sessions will be divided into two groups. A general session will be held on each afternoon of Tuesday and Wednesday; while meetings of the scientific sections will be held on the mornings of those days. The complete scientific program of both the general and the section meetings is printed on the following pages.

THE COMMITTEE ON SCIENTIFIC WORK:

Chairman, Arthur J. Bedell, M. D., Albany

John Wyckoff, M.D., New York
Charles W. Webb, M.D., Clifton Springs
Onslow A. Gordon, Jr., M.D., Brooklyn
Marshall C. Pease, M.D., New York
Conrad Berens, M.D., New York
Noble R. Chambers, M.D., Syracuse
Earl D. Osborne, M.D., Buffalo
Arthur T. Davis, M.D., Riverhead
Luther F. Warren, M.D., Brooklyn

GENERAL SESSIONS

Presiding, William H. Ross, M.D., President, Medical Society State of New York

Tuesday, June 2nd at 2:00 P. M.

Place of Meeting, Ball Room, Hotel Syracuse

Address by the President of the American Medical Association, William Gerry Morgan, M.D., Washington, D. C. (By invitation.)

SYMPOSIUM ON PSYCHOPATHOLOGY AND PSYCHOTHERAPY

Introductory remarks, Smith Ely Jelliffe, M.D., New York City.

1. "In Childhood and Adolescence," Frankwood E. Williams, M.D., New York City.
2. "In Neuroses and Psychoses," Abraham A. Brill, M.D., New York City.
3. "Internal Medicine," Smith Ely Jelliffe, M.D., New York City.

Wednesday, June 3rd at 2:00 P. M.

Place of Meeting, Ball Room, Hotel Syracuse

1. "General Survey," Wells P. Eagleton, M.D., Newark, N. J. (By invitation.)
2. "Surgical Aspects." Albert G. Swift, M.D., Syracuse.
3. "Treatment and After Effects," Foster Kennedy, M.D., New York City.

SECTION ON MEDICINE

Chairman.....John Wyckoff, M.D., New York City
Secretary.....David A. Haller, M.D., Rochester

Tuesday, June 2nd at 10:30 A. M.

Place of Meeting.....Hotel Syracuse

1. "Gall Bladder Physiology, etc.," Lester Levyn, M. D., Buffalo.
2. "The Treatment of Adrenal Insufficiency by the Use of Cortical Extracts," Joseph A. Hartman, M. D., Buffalo and Clayton W. Greene, M.D., Buffalo.
3. "The Nature and Treatment of Non-specific Ulcerative Colitis," Ascher Winkelstein, M.D., New York City.

Wednesday, June 3rd at 9:00 A. M.
Place of Meeting.....Hotel Syracuse

1. "Coronary Occlusion," Alfred M. Wedd, M.D., Clifton Springs.
2. "The Use of Potassium Sulphocyanate in the Treatment of Hypertension," William Goldring, M.D., New York City.
3. "The Present Status of Quinidine Therapy," Edwin P. Maynard, M.D., Brooklyn.

SECTION ON SURGERY

Chairman..... Charles W. Webb, M.D, Clifton Springs
Secretary..... Arthur M. Wright, M.D., New York City

Tuesday, June 2nd at 10:30 A. M.
Place of Meeting.....Hotel Syracuse

1. "Uroselectan—A New Method of Visualizing the Upper Urinary Tract," Lantern Demonstration, Oswald Swinney Lowsley, M.D, New York City.

Discussion by George W. Stark, M.D., Syracuse.

2. "Exophthalmic Goitre in Children," George E. Beilby, M.D., Albany; James G Carlton, M.D., Albany.

Discussion by Martin B. Tinker, M.D., Ithaca.

3. "Plastic Surgery, Its Uses and Limitations," Lantern Demonstration, Clarence R. Straatsma, M.D., New York City.

4. "Fixation of Fractures by Removable Metallic Lag Bolts," Lantern Demonstration, Homer J. Knickerbocker, M.D, Geneva.

Discussion by Ross G. Loop, M.D., Elmira.

Wednesday, June 3rd at 9:00 A. M.
Place of Meeting.....Hotel Syracuse

SYMPOSIUM ON ACUTE ABDOMEN

1. "Acute Abdomen from the Surgeon's Point of View," William D. Johnson, M.D., Batavia.

2. "Acute Abdomen from the Internist's and Practitioner's Point of View," Clayton W. Greene, M.D., Buffalo.

3. "The Present Status of Acute Appendicitis in a General Hospital. "A Résumé of One Year's Admissions for Appendicitis," John J. Morton, Jr., M.D., Rochester.

4. "Post-operative Ileus, Its early Recognition and Control," Donald Guthrie, M.D., Sayre, Pa. (By invitation.)

Discussion by Stanley R. Hare, M.D., Batavia, Alfred K. Bates, M.D., Auburn.

SECTION ON OBSTETRICS AND GYNECOLOGY

Chairman..... Onslow A. Gordon, Jr., M.D., Brooklyn
Secretary..... George H. Bonnefond, M.D, Utica

Tuesday, June 2nd at 10:30 A. M.
Place of Meeting.....Hotel Syracuse

1. "Uterosalpinography with Pneumoperitoneum," Lantern Demonstration, Arthur S. Unger, M.D., New York City.

2. "Dilatation and Its Interpretation," Paul T. Harper, M.D., Albany.

3. "Judgment in Gynecological Problems," George B. Broad, M.D., Syracuse.

4. "The Responsibility of the General Practitioner in Menopausal Bleeding," James E. King, M.D., Buffalo.

Wednesday, June 3rd at 9:00 A. M.
Place of Meeting .....Hotel Syracuse

1. "The Ascheim—Zondek Reaction in Immature Rabbits," Ferdinand J. Schoeneck, M.D., Syracuse.

2. "Repair of Second and Third Degree Lacerations of Perineum and Rectocele." A motion picture with sound. Harold O. Jones, M.D., Chicago, Ill. (By invitation.)

3. "The Technic of Elective Version and Extraction with immediate repair to the Birth Canal Injuries," Irving W. Potter, M.D., Buffalo.

SECTION ON PUBLIC HEALTH, HYGIENE AND SANITATION

Chairman.....Arthur T. Davis, M.D., Riverhead
Secretary.....Frank W. Laidlaw, M.D., Middletown

Tuesday, June 2nd at 10:30 A. M.
Place of Meeting.....Hotel Syracuse

1. "Tularemia," Edward Francis, M.D., Washington, D. C. (By invitation.)

2 "Psittacosis," Robert H. Riley, M.D., Baltimore, Md. (By invitation.)

3. "Human Rabies," Melville D. Dickinson, M.D., Rockville Center.

Wednesday, June 3rd at 9:00 A. M.

Place of Meeting.....Hotel Syracuse

1. "Opportunities for Preventive Medicine in New York State," William H. Ross, M.D., Brentwood.

2. "Veterinary Aspects of Undulant Fever," F. J. Devine, D.V.S., Goshen. (By invitation.)

3. "Laboratory Diagnosis of Undulant Fever," Ruth Gilbert, M.D., Albany.

SECTION ON PEDIATRICS

Chairman.....Marshall C. Pease, M.D., New York City
Vice-Chairman.....:Douglas P. Arnold, M.D., Buffalo
Secretary.....Brewster C. Doust, M.D., Syracuse

Tuesday, June 2nd at 10:30 A. M.

Place of Meeting.....Hotel Syracuse

The Section on Neurology and Psychiatry will meet with this Section for the first two papers.

1. "Treatment of Infection of the Central Nervous System by Forced Spinal Drainage." George M. Retan, M.D., Syracuse.

2. "Problem of Cerebral Dominance—Its Influence on Developmental Problems in Children, Particularly in the Acquisition of Language," Samuel T. Orton, M.D., New York City.

Discussion by Bernard Sachs, M.D., New York City, Lloyd H. Ziegler, M.D., Albany.

3. "Recent Advances in Urology—Their Relation to the Management of Children's Diseases," Joseph F. McCarthy, M.D., New York City.

Discussion by George W. Stark, M.D., Syracuse; John Aikman, M.D., Rochester; Roger H. Dennett, M.D., New York City.

Wednesday, June 3rd at 9:00 A. M.

Place of Meeting.....Hotel Syracuse

1. "Hirschsprings Disease Treated by Lumbar Sympathectomy," T. Wood Clarke, M.D., Utica.

Discussion by John J. Morton, Jr., M.D., Rochester.

2. "Bacteriophages as a Help in the Treatment of Infections in Children," Ward J. MacNeal, M.D., New York City.

Discussion by Samuel W. Clausen, M.D., Rochester.

3. "A Study of the Prophylactic Value of Various Antirachitic Agents," Adolph G. DeSanctis, M.D., New York City.

Discussion by John Dorsey Craig, M.D.; B. Winston Jarvis, M.D., New York City.

4. "Diagnosis of Intracranial Hemorrhage in the New Born," Clifford G. Grulee, M.D., Chicago, Ill. (By invitation.) Discussion by Edward J. Wynkoop, M.D., Syracuse; Henry L. K. Shaw, M.D., Albany; DeWitt H. Sherman, M.D., Buffalo.

5. "Case Report of Celiac Disease." A. Clement Silverman, M.D., Syracuse.

SECTION ON NEUROLOGY AND PSYCHIATRY

Chairman.....Noble R. Chambers, M.D., Syracuse
Secretary.....Irving J. Sands, M.D., Brooklyn

Tuesday, June 2nd at 10:30 A. M.

Place of Meeting.....Hotel Syracuse

The Section on Neurology and Psychiatry will meet with the Section in Pediatrics for the first two papers.

"Psychiatry in Relation to Literature," Louis J. Bragman, M.D., Syracuse.

Wednesday, June 3rd at 9:00 A. M.

Place of Meeting.....Hotel Syracuse

1. "Tic Douloureux," Henry W. Williams, M.D., Rochester.

2. "Some Comments on the Relationship of Mental Deficiency to Misconduct." Vernon Branham, M.D., Albany.

3. "The X-ray Diagnosis and Treatment of Radiculitis Due to Spinal Arthritis," Lee A. Hadley, M.D., Syracuse.

4. "The Signs and Symptoms of Multiple Sclerosis with Particular Reference to Early Manifestations," Albert G. Odell, M.D., Clifton Springs.

SECTION ON EYE, EAR, NOSE AND THROAT

Chairman.....Conrad Berens, M.D., New York City
Secretary.....Richard T. Atkins, M.D., New York City

Tuesday, June 2nd at 10:30 A. M.

Place of Meeting.....Hotel Syracuse

1. "Roentgenological Studies of the Larynx and Adjacent Structures." Mervin C. Myerson, M.D., New York City.

Discussion by Frederick J. O'Connor, M.D., Syracuse.

2. "Management of Eye Injuries," Nelson S. Weinberger, M.D., Sayre, Pa. (By invitation.)

Discussion by Walter S. Atkinson, M.D., Watertown.

3. "Recent Advances in the Diagnosis and Treatment of Chronic Diseases of the Nose and Throat," George L. Tobey, M D., Boston, Mass. (By invitation.)

Discussion by Richard T. Atkins, M.D., New York City.

4. "Recent Advances in Ophthalmic Surgery," Webb W. Weeks, M.D, New York City.

Discussion by Arthur J. Bedell, M.D., Albany.

Wednesday, June 3rd at 9 00 A. M.

Place of Meeting ....Hotel Syracuse

1. "The Place of the Otorhinolaryngologist in the Treatment of Eye Diseases," E Ross Faulkner, M.D., New York City.

Discussion by Thomas H. Halsted, M.D., Syracuse.

2. "Evaluation of all Etiologic Factors in Eye Diseases, Possibly Secondary to Disease of the Ear, Nose and Throat," James G. Dwyer, M.D., New York City.

Discussion by Searle B. Marlow, M.D. Syracuse.

3. "Tinnitus," Edwin S. Ingersoll, M.D., Rochester.

Discussion by Clyde A. Heatly, M.D., Rochester.

4. "Detachment of the Retina—Its Treatment," Edmond E. Blaauw, M.D., Buffalo.

Discussion by David H. Webster, M.D., New York City.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Chairman..... .....Earl D. Osborne, M D, Buffalo
Secretary..... ...Leo Spiegel, M.D., New York City

Tuesday, June 2nd at 10:30 A. M.

Place of Meeting.. ... .Hotel Syracuse

SYMPOSIUM ON SYPHILIS

1. "Cisternal Puncture: Further Observations on Headache and Practical Value," Morris A. Lyons, M.D., New York City.

2. "The Line Precipitation Test with Spinal Fluids in Neurosyphilis," Joseph J. Eller, M.D., New York City.

3. "The Treatment of Neurosyphilis with Tryparsamide," Harry C. Solomon, M.D., Boston, Mass. (By invitation.)

4. "The Treatment of Early Neurosyphilis," A. Benson Cannon, M.D., New York City.

Discussion by Harry C. Saunders, M.D., New York City; Albert R. McFarland, M.D., Rochester.

Wednesday, June 3rd at 9:00 A. M.

Place of Meeting.....Hotel Syracuse

SYMPOSIUM ON MYCOTIC DERMATITIS

1. "Sporotrichosis: Its Infectivity for Plants and Animals," J. Gardner Hopkins, M.D., New York City.

2. "Fungus Infections of the Hands and Feet: Observations as to Their Incidence in New York City," George C. Andrews, M.D., New York City.

3. "The Treatment of Dermatophytosis: A Résumé of Personal Experiences." Paul E. Bechet, M.D., New York City.

Discussion by Charles M. Williams, M.D., New York City; George M. Fisher, M.D., Utica.

SYMPOSIUM ON ECZEMA

4. "The Reaction of the Skin and Its Secretions in Eczema," Oscar L. Levin, M.D., New York City; Seymour H. Silvers, M.D., New York City.

5. "The Key to the Mechanism of Eczema," Walter J. Highman, M.D., New York City; Samuel M. Peck, M.D., New York City.

Discussion by Howard Fox, M.D., New York City; Jerome Kingsbury, M.D., New York City; Herbert H. Bauckus, M.D., Buffalo.

SESSION ON PHYSICAL THERAPY

Chairman.....*Richard Kovacs, M.D., New York City*

Wednesday, June 3rd at 9:00 A. M.

Place of Meeting.....Hotel Syracuse

1. "The Application and Limitations of Light in Therapy," Brian O'Brien, Ph.D., Rochester. (By invitation.)

2. "Physical Therapy in Traumatic Conditions," Kristian G. Hansson, M.D., New York City.

3. "Treatment of Arthritis," John S. Coulter, M.D., Chicago, Ill. (By invitation.)

4. "The Purposes and Aims of the State Development at Saratoga Springs," Carl R. Comstock, M.D., Saratoga Springs.

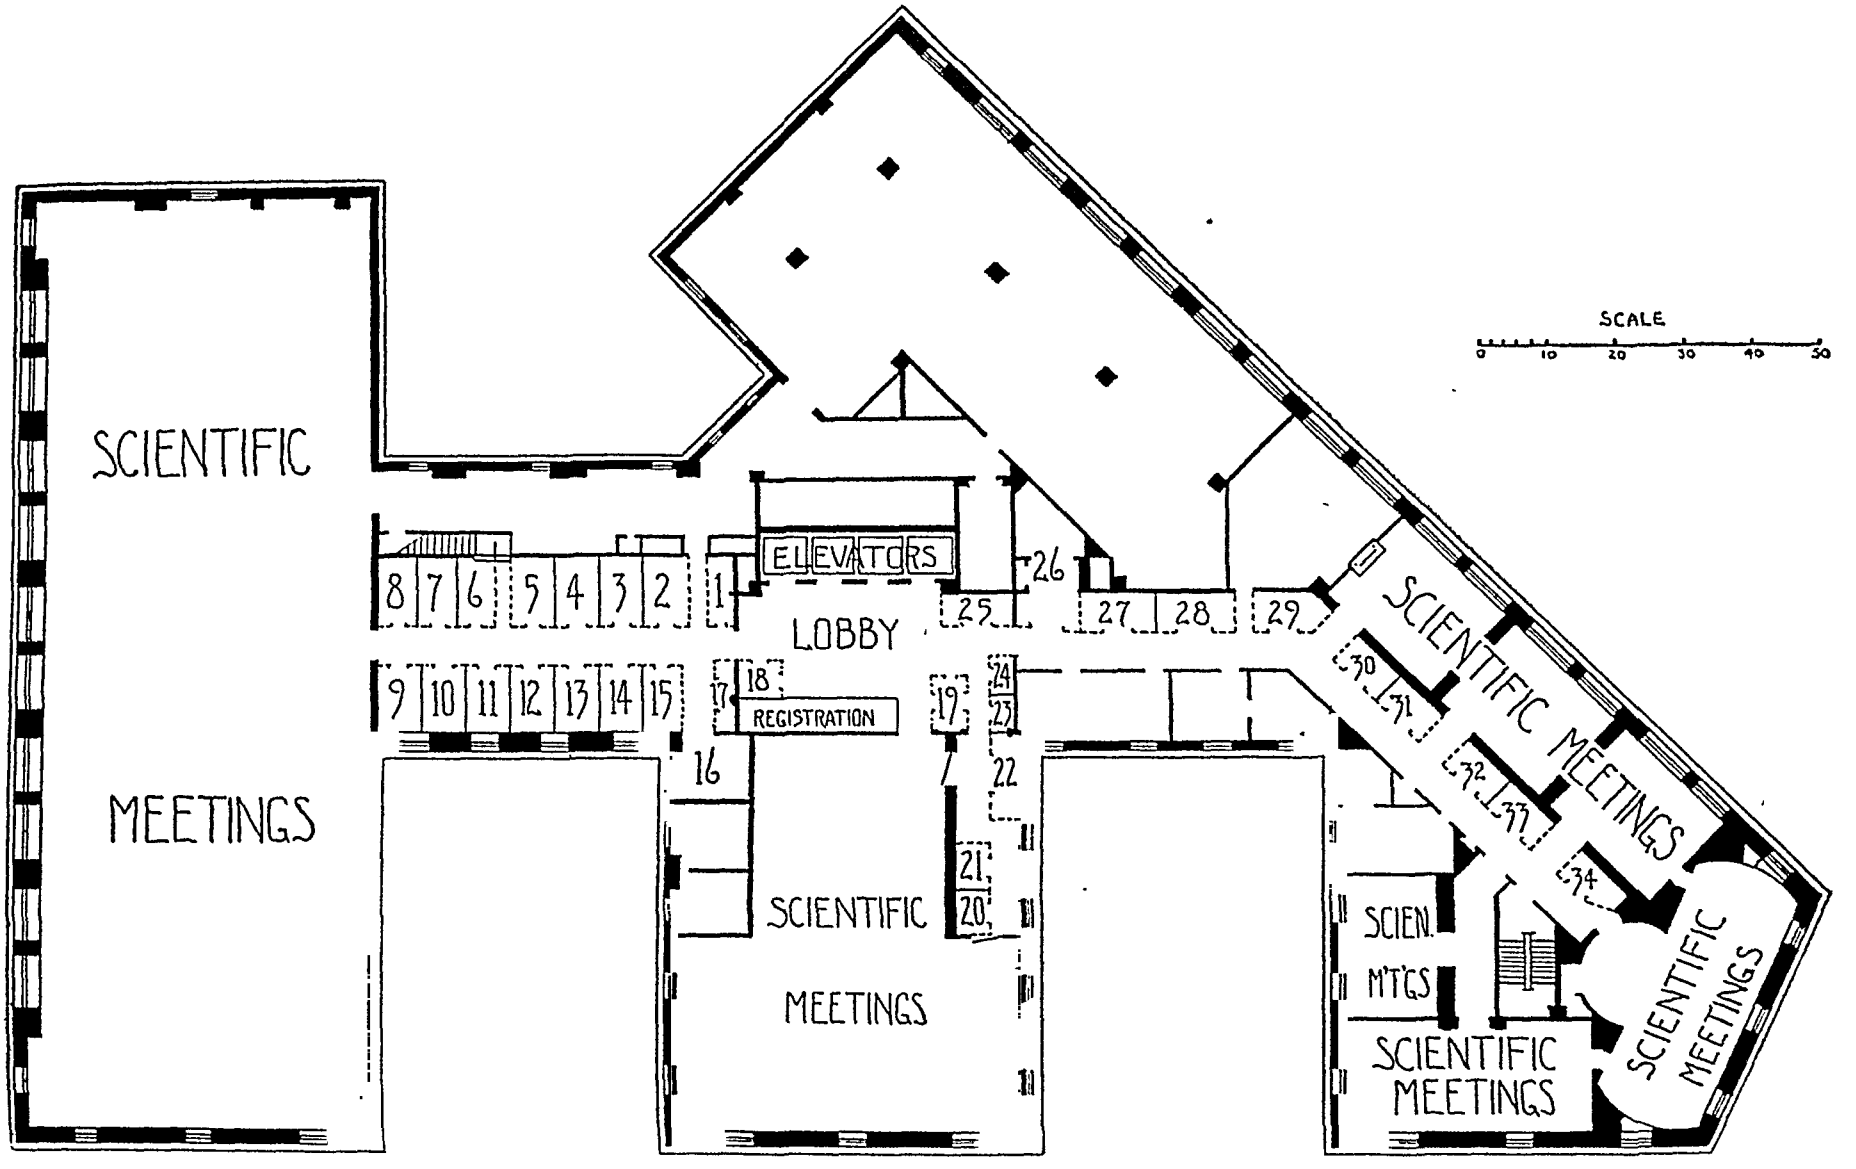

Diagram of Exhibit Hall, Hotel Syracuse, Syracuse, New York.
Annual Meeting, Medical Society of the State of New York, June 1-2-3, 1931

THE TECHNICAL EXHIBITS AT THE ANNUAL MEETING

One of the most pleasing features of the arrangements for the Annual Meeting of the Medical Society of the State of New York to be held in Syracuse June 1-3, 1931, will be the fact that all the different departments of the meeting will be housed in one building,—the Hotel Syracuse The technical exhibits will be displayed on the corridors of the tenth floor, through which all the doctors attending the sessions will pass

The majority of the exhibitors are all friends from among our advertisers, who have supported us in the past years and to whom we are indebted for one of the pleasing features of the Annual Meetings

DESCRIPTIONS OF THE TECHNICAL EXHIBITS

Booth 9—Anglo-French Drug Company (U. S. A.), Inc., New York N Y, will show motion pictures of all types of Surgery including that of the Head Neck and Thorax under Spinal Anesthesia, by Dr Harry Koster of Brooklyn, N Y

Booth 16—The Cameron's Electric Specialty Company, Chicago, Illinois, will exhibit Cameron's Electro-Diagnostoset, Cameron's (Radio Frequency) Cauterodyne, Cameron's Thermaloop Cautery and Cameron's Electro Cautery A 36-page monograph, profusely illustrated in colors on the use of electric light in the practice of medicine, will be presented free to every physician registering at the meeting, or mailing the coupon in the advertisement on Page xii of the advertising department of this Journal

Booth 23—The Crookes Laboratories, Inc, New York, N Y, will feature a number of their *Collosol* medicinal specialties, particularly *Collosol Argentum, Collosol Manganese, Collosol Iodine* and *Collosol Kaolin* Mr S L Scott, special representative, formerly of London, England will be in charge of the exhibit, and will demonstrate to interested physicians the phenomenon of the Brownian Movement showing the dynamic nature of colloids as represented by a number of Crookes Collosol preparations

Booth 33—Davies, Rose & Co., Boston, Mass An informative and interesting visit may be made here where therapies which are engaging wide attention are being discussed Pills of Stramonium Leaves for the sequelæ of encephalitis, and Trethylene for trigeminal neuralgia are among those which are of particular interest to neurologists

Booth 13—The Denver Chemical Mfg. Co., New York, N Y, will exhibit Antiphlogistine, which was introduced to the medical profession nearly forty years ago, and is now employed by physicians in all parts of the world in the treatment of inflammatory and congestive conditions You are invited to visit the exhibit and take away a package of Antiphlogistine with you

Booth 6—The DeVilbiss Company, Toledo Ohio, manufacturers of Atomizers and Vaporizers for home and professional use, has reserved space No 6

The DeVilbiss Company has in the past year made many improvements in its line of Atomizers Many models have been added which will be of interest to the profession These will all be shown at the Syracuse meeting

Booth 10—The Drug Products Co., Inc., Long Island City, N Y, will display an exhibit including three specialties Bismuth Sodium Gluconate, a water and tissue soluble Colloidal *bismuth for intramuscular use*, Pamol, a Colloidal emulsion of mineral oil, agar agar and psyllium seed overcoming objectionable features of ordinary emulsions of this type, and Pulvoids Digitalis Folium, a preparation of whole leaf Digitalis, standardized by the Cat Method of Hatcher and Brody

Booth 19—The Electro Surgical Instrument Company, Rochester, N Y, pioneers in the field of electrically lighted diagnostic and surgical instruments, will display its complete line

Included in the display will be the following instruments Cystoscopes (Braasch) (David), Urethroscopes (Young), Bronchoscopes (Imperatori), Transilluminators (Gibson) (Sullivan), Procto Sigmoidoscope (Tuttle) (Lynch), Fono faryngoskop (Russell), Non Gag Glottoskop (Russell), Single and Double Table Transformers etc

Booth 29—The Foregger Company, Inc., New York, N Y Oxygen carbon dioxide outfits for those who prefer to make their own mixtures, and for the use of "ready-made" mixtures, will be featured by the Foregger Company, in addition to the Metric and Gwathmey Gas Machines, the Henderson and Flagg Resuscitation Outfits and the Guedel Oxygen Tent

Booth 31—The General Electric X-Ray Corporation, Chicago and New York, will exhibit the Victor Electrocardiograph and a rather complete display of Physical Therapy equipment, including their recently announced prescription type Ultra Violet Quartz Lamp for use in the patient's home, and their new *Micro-Surgical* Diathermy Unit with "Micrometer Control"—an ultra modern compact and portable *surgical unit* for the specialist

Booth 18—Gerber Products, Division of the Fremont Canning Company, Fremont, Michigan, will show Strained Vegetables for infant feeding and special diets. These products have gained wide acceptance by the medical profession and the trade during the two years since being introduced.

Strained, unseasoned, specially prepared, these products are of unusual interest because they offer the physician an opportunity for more perfect control of infant diets and insure uniform, properly prepared feedings.

Booth 1—Granger Calcium Products, Inc., Brooklyn, N. Y., will display Cal-Sal Tablets and Wafers and Paste for infants, and Mineralized Candy, and Alkaline Ash Oatmeal. Their business is based on the well-known facts that many serious diseases are attributable to Acid Ash, or Calcium-eliminating neutral foods; that calcium is the safe alkaline; and the now known fact that complete nutrition can be obtained by the scientific use of the proper commercial salts of the deficient minerals.

The business of the Company is done with dispensing physicians and pharmacists who order on physicians' prescriptions.

Booth 17—Horlick's Malted Milk Company, Racine, Wis., will exhibit its well-known milk preparations. Have you found how grateful patients are for the suggestion of Horlick's Malted Milk Tablets as a relief from the sameness of the Liquid Diet? The tablets have the same nourishing and remarkably digestible qualities as the powder form, possessing all the goodness of full-cream milk, choice wheat, and malted barley.

Horlick's Original Malted Milk in both natural and chocolate flavors, both in powder and tablet form, and Horlick's Milk Modifier, a maltose and dextrin product, will be featured at the Horlick booth.

Booth 22—Industrial Hygiene Exhibit, Division of Industrial Hygiene, New York State Department of Labor. This Exhibit, supported by the State, shows typical diseases resulting from various occupational poisons covered by the Workmen's Compensation Act; also provides literature on industrial hazards and methods of preventing accidents. It consists of twelve descriptive screens, continuous moving pictures, wax models of diseased conditions, special goggle and splinter panels, model of mine generating dust, and preserved silicotic and anthracotic lungs.

Booth 8—The Kalak Water Company of New York will exhibit and physicians are invited to call and test for themselves the palatability of this dependable alkalinizing agent. Visit the Kalak Water booth when you are thirsty or when you suffer from manifestations of acidosis. Kalak Water is not a laxative, and you can partake of it freely with benefit.

If you are interested in a simplified method of rapidly determining the intensity of the urinary acidity, ask the representative at the booth to demonstrate the Kalak Indicators.

Booth 14—Kellogg Company, Battle Creek, Michigan. Doctors are invited to visit Booth 14 where the Kellogg Company of Battle Creek, Michigan, has a display of its products, including Kaffee Hag Coffee. This coffee is a carefully selected blend of coffees from which the caffeine has been removed. Doctors will find Kaffee Hag Coffee a satisfactory non-stimulating beverage to suggest for special diets.

Booth 12—The Kny-Scheerer Corporation will occupy Booth 12, where it will exhibit its well-known line of Surgical Instruments and Sundries.

Booth 7—M. & R. Dietetic Laboratories, Inc., Columbus, Ohio, will exhibit Similac, a completely modified milk. A representative will be pleased to answer any questions pertaining to its use, either as a complement to breast feeding or as a complete diet for infants deprived of breast milk.

Booths 3 and 4—Mead Johnson & Co., Evansville, Ind., will have on exhibit its complete line of infant diet materials including Mead's Dextri-Maltose, Mead's Cod Liver Oil, Mead's Viosterol, Mead's Recolac, Mead's Non-Curdling Powdered Protein Milk, Mead's Non-Curdling Powdered Lactic Acid Milk and Mead's Powdered Yeast.

Mead's Cereal will be introduced. A cereal rich in vitamins and minerals will undoubtedly be received with deep interest by physisians.

There will also be for the examination of physicians a complete line of Mead's services such as diets for older children, height and weight charts, etc., all of which are free to members of the medical profession in any quantity desired.

Booth 25—Mellin's Food Company, Boston, Mass. An exchange of ideas and opinions relative to the feeding of infants and the preparation of nourishment for adults requiring a restricted diet is of much value, particularly in view of the recognized importance of selecting the food material best adapted to the individual requirements. The Annual Session of the Medical Society of the State of New York affords an opportunity for such discussion not only in the various sections but in the exhibit hall where representatives of the Mellin's Food Company will await physicians' questions and be ready to discuss the subject matter from the maker's viewpoint.

Booth 34—The Merrell-Soule Company, Inc., New York, N. Y., is exhibiting its group of powdered milk products for infant feeding and child diet. Klim—the powdered full cream cow's milk—will be served ice cold, and its application to the general problem of nutrition described, with particular reference to high caloric diets for underweight children. Since Klim is the most economical powdered milk offered the medical profession, its use has a very real appeal to the patient of moderate means. Be sure to get your glass of Klim and explanatory literature

Booth 15—The Mutual Pharmacal Company, Inc., Syracuse, N. Y. will exhibit products of their laboratory at Booth 15.

The Mutual has an enviable reputation for the dependability and appearance of their products and the exhibit is representative of these qualities. Physicians are cordially invited to visit the booth.

Booth 32—The Pelton & Crane Company of Detroit, Michigan, will show the new Pelton Automatic Autoclave, together with other Pelton Adjustable-Automatic Sterilizing Equipment. Also on display is the Pelton line of Surgical Cuspidors, and the new Pelton Syringe Sterilizer with removable procelain enamelled boiler.

Booth 28—S. M. A. Corporation, Cleveland, Ohio. Complete details concerning S. M. A. service may be obtained at their booth. Representatives will explain the special spraying process for producing all powdered products of their laboratory. They will also tell about the special packing process for Protein S. M. A. (Acidulated) powder and Smaco Products that accomplishes the removal of destructive oxygen present in the absorbed film of air on the surface of the milk particles responsible for the development of rancidity.

Booth 2—E. R. Squibb & Sons, Brooklyn, N. Y., extend a cordial invitation to physicians attending the Syracuse Meeting of the Medical Society of the State of New York, to visit the Squibb Booth in which will be featured a new potent concentrate of the cod-liver oil vitamins, a physiologically tested follicular hormone preparation, and a chemo-therapeutic agent for the treatment of genito-urinary infections. Competent representatives will be in attendance to furnish information concerning any Squibb product.

Booths 20 and 21—The State Department of Health. The milk control exhibit of the State of New York Department of Health is interesting and instructive. An automatic moving picture shows the department's laboratory busses at work. Materials for making standard plate counts and direct microscopic counts of milk are also shown, together with posters giving facts concerning New York State milk control work.

Booth 27—Tailby-Nason Company, Boston, Mass., will introduce an International Delegate to the Annual Meeting of the Medical Society of the State of New York. This distinguished visitor and ally to the American Medical Profession hails from the Lofoten Islands of Norway. The delegate is next to the largest cod fish ever caught and was taken from the Lofoten Waters by Nason & Co., producers of Nason's Palatable Cod Liver Oil. His weight was over sixty-five pounds. His liver made nearly three pints of Nason's light golden, sweet and palatable oil. This Giant Cod is receiving at Booth 27 and is an important part of Tailby-Nason's exhibit of Nason's Palatable Lofoten Cod Liver Oil. Please call and see the distinguished visitor.

Booth 30—George Tiemann & Co., New York, N. Y., will exhibit, in addition to a full line of surgical instruments, its "velvet eye" soft rubber catheters, and colonic tubes, made of the famous Tiemann rubber compound, in a complete range of sizes. Among the worthwhile novelties are the nasal punches made in miniature sizes to fit the universal handle. These have proven very useful and popular. George Tiemann & Co. have standardized some of the popular types of artery forceps, etc., with the result that they can offer chromium plated quality instruments at the price of ordinary ones. This line will also be included in the exhibit.

Booth 11—Petrolagar Laboratories, Chicago, Illinois, will present Scientific Medical Motion Pictures in a beautiful modern display.

Visitors may relax and devote uninterrupted attention to this splendid library of films of international reputation. The list comprises twelve exceptionally instructive subjects. Presentation before accredited medical groups may be arranged for any place or date without charge.

Booth 5—The Westinghouse X-Ray Company, Inc., Long Island City., N. Y., will exhibit two pieces of apparatus which are of wide popular interest to the medical profession at the present time. The first of these—the Westinghouse Model F Endotherm—for electrosurgery, called by newspaper writers the "Electric Knife," will be demonstrated continuously during the meeting. The other—the Westinghouse Sinutherm—is a unique new development which makes possible the simultaneous application of diathermy and low voltage therapeutic currents with a single pair of electrodes, as well as the application of either modality separately.

The new Westinghouse Mobile Bedside *x*-ray Unit, also the Westinghouse Myostat—Galvanic and Wave Current Generator, will be shown.

THE CITY OF SYRACUSE—ANNUAL MEETING JUNE 1-3, 1931

The early history of Syracuse centers particularly around the salt industry, and for that reason it is often spoken of as the Salt City. The principal business thoroughfare is known as Salina Street. While production of salt no longer occupies the foremost place among Syracuse industries, salt coming from the wells south of the city is still an important and necessary part of the enormous chemical industry, known as the Solvay Process Company. On the land where the salt wells are located the Solvay Process Company operates an excellent dairy from which comes the highest grade of certified milk. Syracuse and the surrounding country is known all over the world for its excellent dairies. Milk is produced and cared for by the most modern methods. The standards set by the Syracuse Department of Health are unusually high which account in no small way for the remarkable health record of the city. Any physician who has the time and opportunity should visit some of the numerous dairies near Syracuse.

The Central City of New York is located in the midst of lakes, some of the most beautiful being called the Finger Lakes. From one of these, Skaneateles Lake, nineteen miles to the west, comes the sparkling water which supplies the city. No place in the world can boast of a better water supply. The scenery in this adjacent lake district is unsurpassed in beauty and grandeur. It is not far, less than one hundred miles, to the world famous playground and beauty spot of the Saint Lawrence River, the Thousand Islands.

Much of the acreage of the city proper is given over to parks some of which are very beautiful. Located in Thorndon Park is one of the most famous rose gardens. Visitors are asked to make a special note of this. It is within easy reach, about one mile east of the center of the city.

The many buildings of Syracuse University and the grounds upon which they are located will interest the visiting physicians. With an enrollment of more than five thousand students one will find all of the numerous activities of a modern, progressive university.

Modern hospitals and the College of Medicine of Syracuse University have for scores of years made the city one of the leading centers in medical education. Physicians will profit by visiting these institutions. Many of them are new. All of them are only a short distance from the hotels. Particularly impressive is the hospital and medical center in the University district. If you care to visit the general or special hospitals or any of the numerous clinics, the local physicians will see that your wish is fulfilled. The medical supervision of school children and the University student health service are public health activities exceptionally well organized. Should you be interested, representatives from these services will gladly accompany you and acquaint you with the activities.

With the city's adequate transportation, hotel facilities, numerous industries, golf courses, theaters, and unusual attractiveness, it is not surprising that Syracuse has become popular as a convention city. While famous for its industries, beauty, University, and school system, it is proudest of all of its health record. The united efforts of the citizens of Syracuse, especially the local medical profession, have resulted in one of the healthiest cities in the world. Many visitors interested in all phases of public health come to Syracuse annually to study the methods which have proved so successful. O. H. W. MITCHELL.

RECREATION IN SYRACUSE

Many physicians will plan for recreation and relaxation when they attend the Annual Meeting. The following facts regarding the recreation facilities of Syracuse are taken from the Convention Publicity and Tourist Bureau of the Syracuse Chamber of Commerce:

Close to Syracuse are many beautiful spots, any or all of which should be seen by every visitor to Syracuse. There are a number of delightful waterfalls, lakes and scenic features which will well repay a day or more stop-over in Syracuse for the purpose of seeing them. Listed below are those which are most easily accessible by motor.

Green Lake State Park at Fayetteville on the main highway to Utica, approximately eight miles east of the city. This park contains Round Lake and Green Lake.

Chittenango Falls, near the village of the same name and but a short distance from the main highway on the road to Cazenovia.

Cazenovia Lake, one of the most delightful summer resort points in Central New York.

Edwards Falls, near Manlius, between Fayetteville and Cazenovia.

Clark Reservation at Jamesville containing Green Lake. This is very unique from a geological standpoint.

NEWS NOTES

LEGISLATION

BULLETIN No. 10—MARCH 25, 1931

The osteopathic bill came up in both houses yesterday, March 24th, for final vote. It appeared in the Senate first and was passed with practically no debate, and by a short roll call. The following requested that they be recorded in the negative:

Mr. Berg
Mr. Hastings
Mr. Hofstadter
Mr. Howard
Mr. Knight
Mr. Lord
Mr. Love

Immediately the Senate bill was sent to the Assembly, where later in the day Mr. Tellier had his bill stricken from the calendar and the Fearon Senate bill substituted. After a brief discussion Mr. Cuvillier moved that the bill be recommitted. His motion was lost and Mr. Tellier asked then that the bill be passed. It was lost by a vote of 81 to 55. A record of the vote follows:

Ayes

Mr. Abbott
Mr. Alterman
Mr. Austin
Mr. Bernhardt
Mr. Byrnes
Mr. Canney
Mr. Davis
Mr. Dineen
Mr. Dunmore
Mr. Esmond
Mr. Falk
Mr. Gamble
Mr. Garnjost
Mrs. Graves
Mr. Hartshorn
Mr. Hathaway
Mr. Hewitt
Mr. Higgins
Mr. Hutchinson
Mr. Jenks
Mr. Killgrew
Mr. Lewis
Mr. Mandelbaum
Mr. Marks
Mr. McKay
Mr. Merriam
Mr. Miller, F. G.
Mr. Mittler
Mr. Moffat
Mr. Pack
Mr. Palmer
Mr. Paris
Mr. Pease
Mr. Piper
Mr. Porter, F. L.
Mr. Porter, H. E. V.
Mr. Potter
Mr. Rice
Mr. Richtmyer
Mr. Riley
Mr. Sargent
Mr. Searle
Mr. Sheldon
Mr. Steingut
Mr. Stephens, J. E.
Mr. Stevenson
Mr. Stockweather
Mr. Swartz
Mr. Tellier
Mr. Thistlethwaite
Mr. Thompson
Mr. Vaughan
Mr. Wemple
Mr. Whitcomb
Mr. Whitney

Nays

Mr. Reoux

Mr. Smith, R. B.
Mr. Smith, W. F.
Mr. Stone
Mr. Streit
Mr. Sullivan
Mr. Taylor
Mr. Theodore
Mr. Turner
Mr. Whittaker
Mr. Winters
Mr. Zimmerman

A word of comment with regard to this bill is appropriate. It was announced in both houses that the bill was drawn by Augustus Downing, ex-Deputy Commissioner of Education, and that the osteopaths took identically the same examination under the Regents as the medical men and, therefore, the bill was not undesirable and should be passed. In the Senate Dr. Love spoke against the bill, citing that although physicians and osteopaths took the same examination under the Regents, they were obliged to present different credentials before entering the examination, the physicians being asked to give evidence of having taken two years pre-medical work in a college and having passed one year's study each in pharmacology and materia medica.

In the Assembly Mr. Marcy, of Buffalo, made the principal address and appealed to the Assembly to defeat the bill on t[illegible] that to pass it would be to lower [illegible] tional standards established and jea[illegible] tected by the Regents. He stated bill were passed it would be used [illegible] dent for future appeals, not only by [illegible] paths themselves but by other [illegible] explained the fallacy in the claim [illegible] groups took the same examinatio[illegible] announced that the Board of [illegible]

filed an opposition to the bill while it was still in committee. Therefore, we feel that every physician reading this bulletin—and especially the county chairmen—should appreciate that those who voted against the osteopathic bill felt that they were supporting physicians and guaranteeing to the public the quality of medical service rendered.

We urge that every man whose legislators voted against this bill write immediately to them, expressing his appreciation of the support they have given. Please do not neglect this; it is a small matter, but it will mean a great deal to them and will, likewise, mean a great deal to us later. The chiropractic bill has not yet come upon the calendar so when you write, make a point of asking that this bill be accorded a similar fate.

TO COUNTY SOCIETY LEGISLATIVE CHAIRMEN

March 26, 1931.

There is enclosed a copy of the revised Wicks-Hutchinson bill. Please note the extensive revision which has been made. The Committee will appreciate your immediate comments on this late print.

The last print number for the Porter chiropractic bill is Assembly 2573. This bill will be voted upon Monday night. You will recall that it contains no waiver clause such as the bills of preceding years, but it is particularly objectionable in that it provides for the appointment by the Regents of a special examining board. Advise your legislators immediately, because we find from conversation that many of them are inclined to think the chiropractors need regulation such as this bill provides. Among these legislators are some of our closest friends. Promptly disabuse their minds of this impression.

TO COUNTY SOCIETY LEGISLATIVE CHAIRMEN

March 30, 1931.

Enclosed you will find the following bills:

Senate Int. No. 1788-Dunnigan, to amend the vehicle and traffic law, in regulation to requiring physical examinations of applicants for licenses to operate motor vehicles.

Senate Int. No. 1842, Print No. 2231-Wicks. This bill incorporates certain parts of Mr. Wicks' previous bill, Senate Int. No. 993, known as the Wicks-Hutchinson bill.

Senate Int. No. 1843, Print No. 2232-Wicks, incorporates another portion of the previous Wicks-Hutchinson bill.

You will note that the original bill has been broken into three parts thus far. One is the amended bill in the Assembly by Mr. Hutchinson, Print No 2638, and the other two are the ones named above.

Study carefully Senate bill Int. No. 1842, where you will find stated the powers of the Public Health Council.

Let us have your comments immediately, because the legislature may adjourn this week.

Very truly yours,
HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY.
Committee on Legislation.

BULLETIN No. 11—MARCH 31, 1931

The Assembly reached the Porter Chiropractic bill last night and passed it by a vote of 78 to 57. 77 votes are required for passage, so you can see that the bill barely got by. We were very much surprised at some of the affirmative votes that were cast and are sure that you will be. There is beneath a statement of the vote. The bill now goes to the Senate, where it will rest with the Education Committee. We hope that we can keep it there until the legislature closes, but do everything that *you* can to keep it there—write or telegraph to the members of the Education Committee, the chairman of which is Senator Webb. You have the rest of the names in your white book. Also send wires to Senator Knight and Senator Downing:

New Bills

Senate Int. No. 1762—Wicks (Assembly Int. No. 2037—Hartshorn), amends the State Charities Law relative to the use of the sign "Clinic" or other words to the same effect. When we sent out the bill, we called attention to the fact that in the vicinity of large industries, particularly in New York City, it is reported that certain physicians are conducting their offices in the manner of dispensaries, but are not under the Dispensary Law, because they mark their offices as "Clinics" or with some other similar designation. This bill has now passed both houses and goes to the Governor.

Senate Int. No. 1779—Howard, is the companion to Assembly Int. No. 817—Story, which we reported in Bulletin No. 4; providing no hospital supported wholly or partly at public expense shall charge for medical services given while operating a clinic to which public is invited. The bill is still in committee in both houses.

Senate Int. No. 1788—Dunnigan, adds a new section to the Vehicle and Traffic Law, requiring all applicants for licenses or renewals thereof to pass a medical and physical examination by a physician employed by motor vehicles bureau. This bill may be too exacting to meet with general approval, but certainly there is need for some legislation along this line. We all know that there are color blind men driving cars; others who have very defective vision, and some with defective hearing, all of which can readily be detected by physical examination.

Senate Int. No. 1842—Wicks (Assembly Int. No. 2291—Hutchinson), adds to the Public Health Law relative to enforcing sanitary code, to laboratories, inspection of State institutions and parks, to county health districts, pollution of waters, and empowering the State Commissioner to conduct experiments to discover economical and practicable methods for eliminating or disposing of industrial wastes and sewage. Referred to the Health Committee.

Senate Int. No. 1843—Wicks (Assembly Int. No. 2290—Hutchinson), amends the State Finance Law relative to fiscal supervision of state reconstruction home at West Haverstraw and hospital for treating incipient pulmonary tuberculosis at Ray Brook and transferring appropriations made therefor. Referred to the Finance Committee.

These two bills are parts of the original Wicks-Hutchinson bill. It has seemed wise to break the old Wicks-Hutchinson bill into smaller bills. In the Assembly Mr. Hutchinson still carries what is left of the original W-H bill, under Print No. 2638. This bill provides principally for the acquisition of land, the establishment of state tuberculosis hospitals, and the treatment of venereal diseases.

The Committee has carefully studied these three bills and feels that they deserve our support. With the exception of section 20-b in Senate bill Int. No. 1842, Print No. 2231, and Assemly Int. No. 2291, Print No. 2780, which provides for the creation of county boards of health and specifies that three of the seven members shall be physicians, there is no reference to the county health unit. Probably another bill will be created carrying the remaining part of the original Wicks-Hutchinson bill.

Action on Bills

Assembly Int. No. 1864—F. L. Porter, permitting the health board of a consolidated district to include in estimate of expenses sum for employing a nurse in connection with business of lying-in asylum and for public health work, has passed the Assembly and is reported out of committee in the Senate.

Assembly Int. No. 1887—Gimbrone, amending the Public Health Law requiring health officers hereafter appointed in cities of more than 50,000

to devote entire time to duties of office and not engage in the practice of medicine, has passed the Assembly and is reported out of committee in the Senate.

Adjournment is likely to be not later than April 10th; hence communicate immediately with your legislators regarding these bills, in order that they may be acted upon this year.

SPECIAL BULLETIN, APRIL 4, 1931

STATEMENT ON STATE HEALTH PROGRAM ISSUED BY SPEAKER McGINNIES AND SENATOR KNIGHT

Subsequent to the reading of Governor Roosevelt's special message to the legislature today (April 2nd), in relation to the pending bills to carry into effect the recommendations of the State Health Commission, Senator Knight and Speaker McGinnies issued the following statement:

We have not changed our minds as to the value of the work done by the Special Health Commission. We are enacting into law practically all the important recommendations of the Commission except that requiring the establishment of a county health unit in every county. This particular suggestion, although it has received a great deal of important support, including the approval of the State Medical Society, has also met some opposition from certain parts of the state. Some of this opposition is doubtless based on an imperfect understanding of the exact provisions of the bill, such as the belief stated in various quarters that the bill requires cities to be included in a county health unit, whereas it simply provides that cities may, in their own discretion, at any time, join a county health unit. Also it has been currently reported that the bill would necessarily greatly increase local expenditures for health work; whereas, in fact, it not only would not compel any increase but by reason of State aid would in some instances actually diminish the local tax burden for health purposes, and would simply permit counties in their discretion to establish new, desirable health activities for which the state would reimburse them fifty per cent. While it is true that the bill would *require* the establishment of a county health unit in each county, it would at the same time remove the existing requirement that every town and village, irrespective of size, *must have* a board of health and health officer.

The decision on our part not to press this provision this year is in no sense a disapproval of this recommendation of the State Health Commission, but it seems to the legislative leaders desirable that there should be further opportunity for consideration and discussion of this provision, and that it is desirable that so important a change as this in local health organization should lay over until next year to afford an opportunity for fuller consideration and discussion.

We assume that this recommendation will be renewed next year and that it will have at that time the serious consideration on the part of the legislature which its importance deserves. Meantime, conference and discussion between its advocates and opponents may well result in a greater unanimity of opinion in regard to it.

SPECIAL BULLETIN—APRIL 9, 1931

Up until this morning the Senate Committee on Education had a vote of five to three against reporting out the chiropractic bill. Since then three members of the committee changed their vote and the bill was reported out by the chairman and on the objection of Senator Crawford was referred to General Orders, which, as many of you will recall from past experience, is called the "grave yard." The chiropractic bill for this year is dead.

The Senate has also, within the last hour, passed the portions of the Wicks-Hutchinson bills—Assembly Int. No. 1362, late Print No. 2638; Assembly Int. No. 2290, Print No. 2779—which provide for the erection of three tuberculosis hospitals. These bills have already passed the Assembly and now go to the Governor. The remainder of the Wicks-Hutchinson bills will be put over until next year.

The osteopathic bill still lies on the table in the Assembly, but we know that Mr. Tellier is planning to attempt to take it off tomorrow, when there will be a close call of the house. If you are not certain about how your Assemblyman will vote, wire him immediately at the Assembly Chamber. The vote is not likely to be taken before noon.

HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY,
Committee on Legislation.

CATTARAUGUS COUNTY MEDICAL SOCIETY

(Published at the Request of Cattaraugus County)

A meeting of the Medical Society of the County of Cattaraugus was held March 24, 1931, at the Dudley House, at Salamanca, N. Y. The attendance, in view of weather conditions, was excellent. Twenty-six members were present, out of a total membership of forty-eight. In addition representatives were present from neighboring counties.

After dinner, the meeting was called to order, with the president, Dr. Leo Reinmann, presiding. A short business meeting ensued, which included the election of a new member, Dr. Theodore J. Holmlund, of Cattaraugus.

The meeting was then addressed by Dr. George Eckel, a past president of the Erie County Medical Society. Dr. Eckel dwelt upon certain aspects of the Wicks-Hutchinson Bill, now in the Legislature, and explained the basis of the opposition manifested by the Erie County Medical Society to this bill, and to certain of the recommendations of the Governor's Special Health Commission. He brought out the fact that the actual number of practicing physicians on the commission was only two or three at the most, and that any claim that the findings of the commission represented the viewpoint of the practicing physician was open to doubt on this score.

He pointed out the undesirability of haste in the passage of this particular bill, and depolred the fact that the organized profession was being given very little time or opportunity to acquaint itself with the bill.

He counseled the physicians present to consider his words, and the wording of the bill, very carefully.

Following Dr. Eckel's address a spirited discussion ensued. The following resolution was then introduced by the Committee on Public Relations, and was passed unanimously, with the request that the Journal publish it and the account of the meeting.

WHEREAS, A bill has recently been introduced into the Legislature of the State of New York, this bill being termed the Wicks-Hutchinson Bill, and

WHEREAS, This bill is being actively pushed by various of the officers of the Medical Society of the State of New York, although it has not to our knowledge received the endorsement of the component county medical societies of the State Medical Society, or the House of Delegates thereof, and

WHEREAS, This aforesaid bill provides for the almost immediate institution of COMPULSORY county health departments in New York State outside of Greater New York, and

WHEREAS, Such compulsory institution of county health units has not to our minds received sufficient study from the organized medical profession as to their desirability, necessity, or efficiency, and

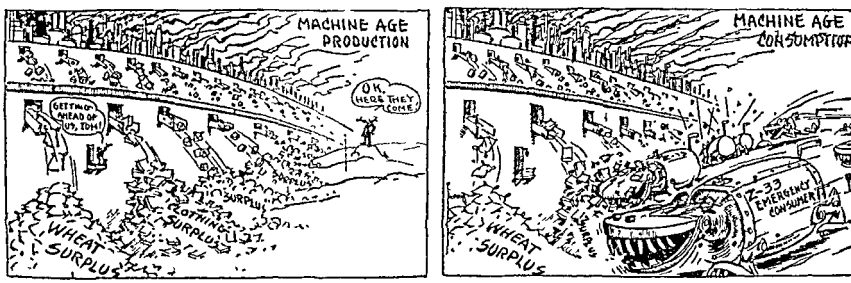
WHEREAS, Our experience in Cattaraugus County with a county health unit has not as yet completely convinced us of the tremendous advantages claimed by its advocates for the compulsory county health unit plan, and

WHEREAS, There is apparent a very marked haste in the speeding of this bill through the various legislative channels; with the report of the commission advocating the bill, the activities of the State Medical Society promoting the bill, and the introduction of the bill into the Legislature being almost simultaneous phenomena,

Now, Therefore, Be It Resolved, That the Medical Society of the County of Cattaraugus, in meeting assembled March 24, 1931, go on record as opposed to the Wicks-Hutchinson Bill at the present time, until provision is made for further and complete study of its provisions by the organized physicians of New York State, and be it further

Resolved, That the Medical Society of the County of Cattaraugus record its opposition to the COMPULSORY nature of this bill, and record itself in opposition because no provision is made in this bill for the abolishment of a county board of health should it prove unnecessary or inefficient, and be it further

Resolved, That the Cattaraugus County Medical Society deplore the activities of officers of the State Medical Society in advocating the passage of this bill before a meeting of the House of Delegates of the State Medical Society has occurred, and complete opportunities have been afforded the medical profession of the State for study of the bill in question, and be it further



Resolved, That copies of this resolution be immediately sent to the Executive Officer of the State Medical Society, with a request for prompt transmission to the various officers and committees of the State Medical Society, and to the *Journal* of the Medical Society of the State of New York, with request for publication, and to the various county medical societies in the State of New York.

Carried: Ayes, 26; nays, 0. Total membership, 48. Total present, 26.

RAYMOND B. MORRIS,
Secretary.

THE DAILY PRESS

CONVENTIONALIZED HEALTH PUBLICITY

New York Herald Tribune, March 17, 1931

Are we approaching a machine age in the production and distribution of health service? How much health service can an individual or a community absorb? How many pounds of spinach should a child eat in order to attain a maximum of growth and vigor? Are we approaching a machine method in the preparation of health talks? Must we pour a few scientific facts into a lecture mill, and take out a certain number of inches of talk for a school child to consume? Answer these questions, ye who can.

LEARNING TO READ

How long does it take a school boy to learn to read? Two or three years is the time usually given as the minimum; but the New York *Times* of March 9 has the following description of an attempt to teach Blackfeet Indians to read in two weeks:

Today is to be opened on the Blackfeet Indian Reservation what is called an "illiteracy clinic." The object is to determine how much adult literate Indians can learn in two weeks under specially trained teachers. There will be 200 Indians, men and women, among them Chief Bird-Rattler, Fish-Wolf-Rose and Mary-Wades-in-the-Water. All have a good average of intelligence and will undergo intensive training in reading and writing, with a touch of arithmetic.

"The textbook will be one prepared under the auspices of the National Advisory Committee on Illiteracy, of which Secretary Wilbur is chairman. Its seventy-two lessons are intended to enable the illiterate Indian to read *The Blackfeet News,* which is to be published during the 'clinic.' Many will see in it for the first time their own names in print.

"The Indian Bureau and the local district of Browning, Mont., are cooperating with Secretary Wilbur in this experiment. The hope is to prove that literacy can be gained in a matter of weeks rather than years. If the illiterate adults of the aboriginal race pass their examinations, they will get certificates on the last day of school, which is to end with an Indian feast. But they will also be challenging every illiterate in the United States, their reservation giving an example to every other community. The demonstration will be followed with interest by all the States that are now carrying on literacy campaigns."

It seems to us that about one hundred years ago, a Choctaw Indian invented a syllabic alphabet of about 80 characters with which the men of his tribe learned to read in a day or two.

THE RANGE OF SIGHT

The unaided sight of man is probably inferior to that of many lower animals; but the microscope and telescope and other human devices have enabled him to see objects which are hidden from all other creatures. The New York *Herald Tribune* of April 5, in discussing these devices, says:

"The basic devices permitting man to project his feeble sense of sight into hidden scientific wonders have been gathered together for the first time in a display at the Exhibition of the Science and Art of Color at the Museum of Science and Industry in East Forty-second Street, New York. The ten machines are:

1. The stroboscope, which slows up the motion of objects moving too swiftly for the eye to see;
2. the oscilloscope which catches the movement of objects too vibrant;
3. the microscope which reveals the infinitely small;
4. the telescope to see distant objects;
5. the radiometer, which detects the invisible infra-red, or heat, waves;
6. the photo-cell, which ensnares the unseen ultra-violet radiations;
7. the *x*-ray, which reveals things through opaque materials;
8. the spectroscope, which sorts out the mixed radiation of white light;
9. the pyrometer, which records things too radiant for the eye to gaze upon; and
10. the spectro-photometer, which performs feats of color analysis beyond the power of the human eye."

AN OPERATION FOR SHOW

It seems incredible that any surgeon would perform an operation on a stage before a lay audience, yet that was what a beauty surgeon did on March 12 in the Hotel Pennsylvania, New York City, according to the *New York Herald Tribune* of March 13, which said:

"Three women fainted during the performance of an operation in face lifting at the International Beauty Shop Owners convention at the Pennsylvania yesterday.

"The operation seemed to hurt the audience more than it did the patient, who was a motion picture actress. The 1,200 women in the room were much affected by the actual process of the operating, but the patient conversed cheerily with the surgeon and left the stage after it was over, announcing that it 'didn't hurt a bit.' She had been treated only with local anaesthesia. The room was overcrowded and the precautions taken by the committee were swept away by the audience itself.

"It was said by officials of the convention that very little of the actual operation was visible, as the surgeon was facing the room and working on the side of the patient's face which was away from the audience. The flashing of photographers' lights added to the nervous tension of the onlookers."

SCHOOL OF EVIL

Light on the cause of crime is given in the following editorial in the New York *Herald Tribune* of March 9:

"Some weeks ago Police Commissioner Mulrooney had a few impatient words to say about the way in which the lurid presentation of criminal news makes heroes of gangsters, who are sneaking blackmailers and assassins in his sight, and fires the youth of big cities to emulation. Point is now given to these remarks by the appearance of four small boys, none over twelve years of age, in a Manhattan police court on a charge of playing gunmen with pistols and revolvers, which they had burglarized from a theatrical studio.

"This is not a unique case. It is a common sight in the streets, whether among the tenements or on Park Avenue, to find school children with toy pistols solemnly acting make-believe hold-ups, killings and motor car banditry in parked automobiles. In one sense these games are no more than the modern version of the scalpings, stage-coach robberies and cow-camp duels which the little out-law-worshipers of the last generation acted in the same streets.

"Not one boy in a million who thought he would like to be a bad man or a cattle rustler ever had a chance or a real hope of meeting his heroes in the flesh; while the modern city boy, if he is gaited that way, can meet and attach himself to his heroes almost as soon as he tires of the make-believe of the playground. The responsibility which devolves upon those mediums of publicity that turn jackals into lions, yellow ruffians into bold, dashing denizens of a night club superworld, is infinitely heavier, therefore, than that which used to be fixed upon the dime novel and later upon the cruder Western 'movies.'"

BOOK REVIEWS

THE TREATMENT OF SCHIZOPHRENIA. By LELAND E. HINSIE, M.D. Octavo of 206 pages Baltimore, Williams & Wilkins Company, 1930 Cloth, $3 00.

The term Schizophrenia has replaced that of Dementia Præcox whenever the disease is discussed in better circles. However, the newer terminology has in no way altered either the signs or symptoms, or prognosis of that morbid disorder. It has given, however, a stimulus to younger workers in the field of psychiatry to study the disease in the light of new psychological approach, especially by the psychoanalytic method discovered by the immortal Freud. Dr. Hinsie has had a very rich experience with mental patients as observed in the New York State Hospital system, and is in an authoritative position to formulate new concepts and principles about schizophrenia in the light obtained from his exhaustive studies. He has written an excellent book, limiting his effort in describing the treatment of those schizophrenics who are in the adolescent period, who voluntarily seek treatment, whose psychical symptoms are in the ascendency, who have insight into the fact that their mental processes are abnormal, and who are communicative and willing to follow the directions laid down by the therapist. The method employed in the treatment of these patients is a simplified form of the Freudian method. In eleven chapters, he has surveyed his material in a most comprehensive manner, has pointed out errors in the earlier concepts of the disease process, has given the salient points of psychoanalysis, and formulated a method of managing his other circumscribed group of patients. The book may be properly designated as a milestone in the approach to the treatment of Dementia Præcox. It is also a vital testimonial to psychoanalytic psychology. As a whole, the book is a real contribution to psychiatry, and one which every neurologist and psychiatrist must possess in his library. A chapter devoted to the survey of the literature enhances the value of the book. IRVING J. SANDS.

ASSOCIATION FOR RESEARCH IN NERVOUS AND MENTAL DISEASE. Vol. 6. The Cerebellum: an investigation of recent advances. Editorial Board Frederick Tilney, M.D. and others. Octavo of 649 pages, illustrated. Baltimore, Williams & Wilkins Company, 1929. Cloth, $10.00.

This volume is a compilation of papers presented before the Association for Research in nervous and Mental Diseases, with respect to recent advances in the study of the cerebellum.

The first section is devoted to the morphology of the cerebellum. Dr. Strong points out unsolved problems suggested by cerebellar connections and cerebellar histology. There is then presented a comparative study of the Arbor Vitae and Folial pattern in the mammalian cerebellum with a view toward correlating these forms with the bodily development of a particular species. A similar comparative study of the vermis is presented. Tables and graphs illustrate the quantitative relationship of the proprioceptive tracts in mammals.

The second section is devoted to the physiological and experimental investigation of the cerebellum. Experiments by Rademaker are referred to, in which the cerebellum was completely extirpated in dogs and cats, resulting in atonia shortly after ablation, but only temporary. The reflexes of posture elaborated by Magnus and DeKlein and their relationship to the cerebellum is discussed. Experiments are outlined in which various folia of the cerebellar cortex were stimulated with localized and correlated reaction of various parts of the body.

The third section is devoted to pathological studies of the cerebellar connections. A "tumbling kitten" was the subject of pathological study. It showed an inability to maintain the optimum physiologic posture, that is the position of lying on its belly so that it could bring both legs under it. The animal was born without the tracts necessary for this. The anatomy of the cortico-ponto-cerebellar system is investigated by study of human pathological specimens.

Section four is devoted to clinical studies. The function of the cerebellum is to synergize all motor activities. It acts in relation with the cortex and brain and cord. There is functional localization in the cerebellum. In the vermis are represented, the synergic activities of the trunk. The fundamental defect symptom of a cerebellar lesion is asynergia. There is a study of cerebellar symptomology based on 51 cases of intra-cranial disease verified by operation or autopsy. The most common form of asynergia was disturbance in gait. Almost all fell to the side of the lesion. The next most common form of asynergia was ataxia, also most always on the side of the lesion. There is a detailed discussion of the symptomatology of intra-cerebellar, cerebellar-pontile angle tumors and the infra-tentorial tumors with cerebellar symptomatology.

Section five is devoted to treatment (215 cases are reviewed in which 237 operations were performed). The types of anesthesia, method of incision and operative technique are reviewed. Differential diagnosis is carefully gone into. Finally the irradiation of cerebellar tumors is discussed.

This review can hardly do justice to so complete a work. It is of interest to all workers in all branches of medicine and will be a valuable contribution to a better understanding of the cerebellum in its relation to the organism. STANLEY S. LAMM.

ASSOCIATION FOR RESEARCH IN NERVOUS AND MENTAL DISEASE. Vol. 8. The Intracranial Pressure in Health and Disease: an investigation of the most recent advances. Editorial Board Charles A. Elsberg, M. D., and others. Octavo of 519 pages, illustrated. Baltimore, Williams & Wilkins Company, 1929. Cloth, $6.00.

This is Volume VIII of a series of research publications by members of the Association for Research in Nervous and Mental Diseases. There are thirty-eight contributors to this volume, most of them investigators who during the past ten years have added much to our knowledge of the cerebrospinal fluid and its pathways. Many phases of the subject are presented but for the most part the question of pressures, as the title implies, has been the leading thought.

It would not be practical to attempt a review of each article. Suffice it to say that this volume represents at the time of its publication a very good review of what we know about the pressure of the cerebrospinal fluid in health, following the introduction of many kinds of intravenous drugs and during the course of expanding lesions of the brain. To this may be added the articles dealing with changes secondary to abnormal intracranial pressure over long periods of time.

Anyone interested in the subject should read every article of this volume for in no other way could one appreciate the importance of these collected contributions. JEFFERSON BROWDER.

OUR NEIGHBORS

A POPULAR HEALTH MAGAZINE FOR KANSAS

The March issue of the Journal of the Kansas Medical Society says that the establishment of a popular health magazine similar to Hygeia was considered by the Bureau of Public Relations of the Kansas Medical Society at its meeting in January, but decision was deferred until the annual meeting in May. The Journal says:—

"This proposition was submitted to the Bureau of Public Relations at its meeting in January. After some discussion it was decided to leave the matter for final determination at the annual meeting in May. In the meantime in order that a fair estimate may be made of the interest the members of the Society may be expected to take in this kind of a publicity campaign each one will be asked to pledge as many subscriptions as he feels would best serve his interests. Letters will be mailed in a few days to each member of the Society asking him to pledge at least ten subscriptions at fifty cents each."

"The success of such a publication, as a medium for our publicity campaign and as a business proposition depends entirely upon the prompt development of its circulation. To be of any value for publicity and to make the venture financially possible, it should have an immediate paid circulation, covering every section of the state, of at least ten thousand. That is the only problem to be solved and it is easy of solution if the members of the Society are as much interested in the matter of publicity as they should be. There are approximately fifteen hundred members in good standing and if each member will subscribe for ten of his patrons we would have fifteen thousand subscribers to begin with.

"It would be a nice compliment from the doctor to his patient to send him a year's subscription to such a magazine. It would be an excellent investment for a doctor to send a complimentary subscription to each of his families."

RURAL DOCTORS IN TENNESSEE

The rural parts of Tennessee are on par with those of New York State in regard to the number of available doctors, if one may judge from the following editorial in the February *Journal of the Tennessee State Medical Association:*

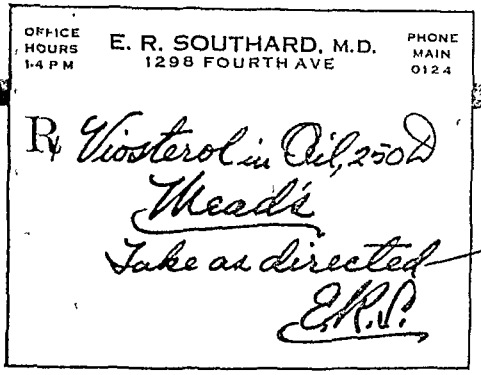
"Some years ago a great cry was raised about the scarcity of doctors in Tennessee. This was ground for the revision of laws governing the licensing of doctors. A tremendous change has taken place in Tennessee since that time. Roads have been built. A car can be driven to most any point that is suitable for human habitation.

"Today we hear greater complain of country doctors and small town doctors being unable to earn a livelihood than we hear of the scarcity of doctors.

"The fact is that rural dwellers will not patronize the old country doctor who still lives among them. They call a doctor from town. The country doctor in several instances has found it necessary to move to town and some will take care of practice he formerly did in the country.

"We have on file a number of requests for information as to good locations in Tennessee for a well prepared practitioner. The cooperation of the profession is requested in placing these men. Please forward complete information as to locations to this office at an early date."

The Medical Society Department of the same journal describes the Medical Society of Blount County, as follows:



"The Blount County Medical Society meets every Thursday night. Last year's report shows 25 members. Total attendance of 605 for the year. One hundred cases were reported; 27 papers read; 103 discussions of papers; 9 clinics presented; 48 regular meetings were held during the year and 1 special meeting; 17 visiting doctors attended the meetings; 3 special addresses were made by visitors."

This would be a remarkable record for a city society, but on writing to Dr. J. A. McCulloch, Secretary of the Society, we found that it was a strictly rural county located in the mountain region. Dr. McCulloch wrote:

"Blount County lies in the Eastern section of Tennessee between the Tennessee River and the Smokey Mountains; and a large portion of the Great Smokey Mountain National Park is in

(*Continued from page* 504)

Blount County. It has a population of 33,989, of whom 5,000 live in Maryville, the County seat, and a like number in Alcoa, an adjacent manufacturing city. Seventeen doctors are listed in Maryville who are eligible to membership in the County Medical Society, of whom fifteen belong to the Society.

"For several years the Blount County Medical Society has met weekly, and is one of only four counties in Tennessee which hold weekly meetings. In 1927 it held 49 meetings; in 1928, 48 meetings; in 1929, 44 meetings; and in 1930, 48 meetings. A program is prepared for six months in advance, and every member of the Society is expected to prepare a paper on some scientific subject at regular intervals.

"A full-time Health Unit is located in Maryville under the direction of the Commissioner of Health for the State, with a full corps of assistants. The County Medical Society is the liaison committee for the County Health program, which is submitted annually for its approval. There is close cooperation between the Medical Society and all civic organizations of the county. Tuberculosis control has been emphasized, and as a result a tubercular sanitorium for children has been established and is being operated by voluntary public subscription. At certain intervals lectures on health subjects and clinics are presented to high school students by the members of the Medical Society. Typhoid, smallpox and diphtheria have been virtually eliminated as a result of the activities of the members of the Society in connection with the local Health Unit. School examinations are conducted during the entire school year, and the correction of defects are referred to the physician. In other words, the Medical Society is responsible for the Health Unit and its work."

It is doubtful that any county in New York State can approach this record even remotely.

HEALTH PROGRAM IN COLORADO

Dr. C. E. Harris, of Woodmen, Colorado, gave a paper before the State Society in which he made original comments on the health program of the State, and said:

"Organized medicine stands today because it has not attempted to erect a towering structure of therapy on a narrow base. It is a comforting thesis which bids us put our own house in order and mind our own business; but it will not stand analysis. We have erred sadly in allowing auxiliary health organizations to slip beyond our control. One of the prime essentials in a reform program is to see that the State Society exercises a strong directing influence over, if not actual de facto control of, lay health organizations. If we can profit by the experience of Iowa, it should

(*Continued on page* 507—*adv. xiv*)

(*Continued from page 506—adv. xviii*)

become apparent that the laity welcome rather than resent such control. We cannot dispense with lay organizations, but they should be directed by those who look at health with the seeing eye.

"Somewhere in Pueblo is a hardware merchant who is qualified to show a well meaning but bootless carpenter the way to better business. He needs no instruction regarding hammer and saw but only advice as to how to make his dollar go farther. Somewhere in Denver is a suburban grocer who ekes out a hand-to-mouth existence. He needs to be told by competent counsel that while he will never succeed as a tradesman, he has a better prospect as an insurance solicitor. Somewhere in Fort Collins is a truck driver with his nose on the grindstone because his wife needs instruction on household economics. At the other end of town is a lawyer's wife who is qualified to show her the way. And the families of the carpenter, grocer and truck driver will have better health when rescued from economic despondency. It is idle to say that there are men in every community who are willing to give salutary counsel. The assistance must be proffered even as we must emerge from our shell of complacency and make known under organization auspices the possibilities of a far reaching health program. When we are willing to preach valiantly the doctrine that good health pays, even at current price schedules, we will hear less furor about the high cost of medical care. Can we reach all who are on the nether side financially? Assuredly not. The thriftless, the incompetent and the congenitally deficient will resent any such program. Again I say, 'Help those who are worth helping.'"

Doctor Harris evidently agrees with the Editor of the NEW YORK STATE JOURNAL OF MEDICINE that the people themselves have a duty in the distribution of medical services to the needy.

CONVICTIONS FOR ILLEGAL PRACTICE IN PENNSYLVANIA

The March issue of the *Pennsylvania Medical Journal* contains an editorial describing the prosecution of quacks by the *Philadelphia Record*.

"At the time of the 1928 session of the State Legislature, our State Medical Society in common with other groups approved annual registration of physicians, the fee being one dollar, to accumulate a fund as was understood for certain matters, one of which was the prosecution of the illegal practitioner. This was deemed necessary because the State does not provide funds to prosecute any one who may be illegally practicing the healing art.

"It is of interest that newspapers at times ac-

"Upon the Advice of My Physician"

THE majority of men and women who come to McGovern's Gymnasium to correct some physical condition are sent there directly by their physicians.

For more and more physicians are realizing the futility of leaving patients to their own resources when exercises are prescribed, and have learned that through individual attention at McGovern's, their instructions will be faithfully carried out.

A work-out will convince you of the superiority of the McGovern Method. Let us send you a guest card. No obligations, of course.

complish more than those whose duty it is to take care of such matters. All credit to *The Philadelphia Record* that secured the conviction of thirty-five illegal practitioners, twenty-six men and eleven women, in Philadelphia, which *The Record* hopes is the beginning of the end of quack healing in Philadelphia. The statements herewith are taken from the files of *The Record:*

"*The Record's* campaign to rid the city of unlicensed practitioners who had been preying on the victims of disease, began in June, 1930, and thirty-five men and two women were held under indictment for trial. The first two of the group came to trial on January 26, and were promptly convicted. The attorneys for the other thirty-five admitted defeat, and advised the district attorney that the next day they would enter pleas of nolo contendere, which meant that they would offer no defense, and simply have their clients throw themselves on the mercy of the Court.

"The first one tried, Otto Bimbler, aged 44, described himself as a naturopath and admitted he had treated thousands of patients. One of the women winesses testified that he had guaranteed to cure her of sterility, the course of treatments to cost $2.50 each, but that she failed to become pregnant. He gave her electric treatments, and pills for many weeks, to cure a blood tumor, which was preventing conception. In the final analysis, two jail sentences, $7,000 in fines, and $519.84 in costs, was the price paid by thirty-two quacks for practicing without a license. Three other healers were put on probation for a year.

"When Emma L. Amonson, a chiropractor, was called, her attorney stated she was intelligent and had an education. 'The more intelligent the less the excuse,' replied the Court. When the Judge was told that Mrs. Amonson had been employed by the State Board of Medical Education and Licensure, he stated 'This is all the more damning.' It appears her husband is still in illegal practice."

The Medical Journal quotes an editorial in *The Record* as follows: "It is of real importance that the blow given to quackery should lead to better protection of the public health in the future.

"Eventually measures should be taken to revise the whole system of licensing practitioners of the various methods of treating disease. But meanwhile there is urgent need for real enforcement of existing law.

"That it is now virtually suspended, that a newspaper had to drag flagrant violators to Court, is due to lack of funds by the State Medical Board.

"It is the duty of the medical profession to insist that the Legislature make adequate appropriations for this purpose, and that the responsible agency rid the State as it can, of unlicensed frauds and incompetents masquerading as doctors."

PSYCHIATRIC EXAMINATIONS OF CRIMINALS IN TENNESSEE

The March number of the Journal of the Tennessee State Medical Association has a leading article by Dr. H. B. Brackin, describing the work of the staff of the Central State Hospital, in Nashville, in examining persons on trial for crimes. The author says:

"We have received fifty-nine patients for observation from the Courts of Tennessee during the last two years and four months. Nineteen of these patients had committed murder; seven had attempted to commit murder; twelve had committed larceny, stealing everything from chickens to automobiles and thousands of dollars worth of diamonds; eight committed forgery, four committed rape, two committed robbery, two broke the White Slave law, two broke the Jones law, one had sex relations with a mare, one committed arson, and one abused women.

"After observing these patients from thirty to sixty days and doing a complete mental and physical examination and all laboratory work indicated, we made a written report in each case and outlined our reasons for saying whether patient was sane or insane. All of our staff signed each report and swore to it before a notary. We always state in the report that we have no interest in the case and receive no fee, and always send three copies of the report; one to the judge, one to the attorney-general, and one to the attorney for the defense. Out of the fifty-nine cases, I am indeed proud to state, our report has been accepted verbatim by the court in 53 of them. Our report was simply read without any of us being present or even summoned. The judge passed sentence according to our statements. If we stated they were insane the court sent them to the hospital for the insane to remain until they recovered and then be returned to court to stand trial, this being according to the Tennessee statute. If we stated they were not insane then they were tried for the crime and if found guilty sentenced to prison, and if not, released. In the other six cases we were subpœnaed and put on the witness stand and merely asked to recapitulate to the jury our written statement, and in each case they followed our recommendations. In other words,

"Nutritional Insurance"

BEMAX

REG. U.S. PAT. OFF.

ENTIRE CEREAL EMBRYO

A
Natural
Vitamin B
Food

VITAMIN B in the diet has been likened to insurance because of its necessity to the normal diet for its own value and its probable aid to other vitamins in combination.

According to medical research, an adequate supply of vitamin B in the diet tends to increase appetite, aid digestion, and improve the process of elimination. Thus it seems not only necessary to general wellbeing, but of importance in the functioning of other vitamins.

As an evidence of this, Hoobler (*Jour. A.M.A.*-2-28-31-676), says: "One should be careful not to overdose with cod liver oil and viosterol unless at the same time an increasing quantity of vitamin B is also added to the diet."

BEMAX is entire cereal embryo, so processed and stabilized as to offer perhaps the richest known source of vitamin B.

the courts of Tennessee, which also includes the Supreme Court, as some reports were for them, have accepted 100 per cent the statements of the staff of the Central State Hospital for the past two years and four months in regard to the sanity or insanity of fifty-nine criminals. This record we feel justly proud of, but do not think our results are on account of our superior ability, but on account of our method. We doubt that our method is used in other states, and we also doubt whether there is the complete cooperation and confidence in any other state between courts and hospitals for the insane."

GRADUATE TEACHING IN RHODE ISLAND

The March issue of the *Rhode Island Medical Journal* devotes an editorial column in reply to the insinuation that the State is deficient in facilities for graduate instruction, and says:

"We have often heard it deplored that there is no 'teaching center' in any Rhode Island medical community, because of the lack of a medical school, in spite of the magnitude of clinical opportunities and the incident wide variety of cases suitable for presentation.

"Perhaps the most attractive approach to the most interesting cases is made possible in the Clinic-Pathological Conferences held on Tuesdays at noon every other week at the Rhode Island Hospital, and to which all members of the profession are most generously welcomed. These are the sort of meetings which seek to present in their entirety from the onset of the patient's illness, through the clinical course of the disease with all laboratory and other data, to the final outcome and the post mortem findings, one or two interesting cases.

"But that which stimulates the most admiration is the care with which these cases are prepared, and the splendid presentation of the material at hand. The story of the case is briefly but most completely outlined. The laboratory work is painstaking and accurate, and the pathological reports are brilliant. Even the histological findings are presented by very beautiful micro-photographs, which not only commend the thoroughness of the microscopical study of the tissues, but portray an admirable technique in the art of scientific photography.

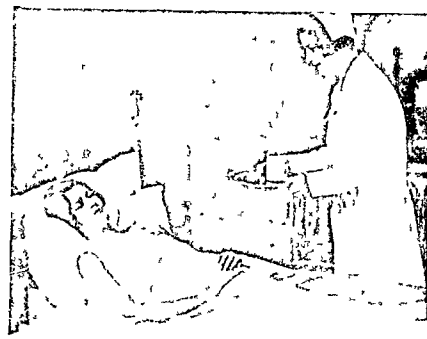
"No doctor in Rhode Island need deplore the lack of teaching facilities here, or thereby excuse his inability to keep abreast of modern medical thought, while we have such splendid meetings as these conferences; and the time and effort necessary in attending them is more pleasantly and profitably spent, and best of all, in the last analysis, our patients receive the ultimate benefit."

JOURNAL OF NEBRASKA

The following data on the *Nebraska State Medical Journal* are taken from the report of the Council meeting contained in the March Journal

"We have followed a consistent policy for years of furnishing three cuts to any article at the expense of the Journal Fund, and we have asked the author to assume the expense of any additional cuts if needed or desired by the author To this we have made exceptions in cases of a large number of cuts to an article. In such cases we have assumed about one-third of the expense A case in point is an article published in the November number containing 27 cuts

"The publication board has, however, decided at this meeting that the practice referred to in the last paragraph should not be continued



"If the Councilors will continue the appropriation of the sum of $1.50 from the dues of each member to the Journal Fund, we feel that we can get along quite comfortably, and give the profession a Journal as creditable as most of them"

The financial statement of the Journal is as follows:

"January 1, 1930 to December 31, 1930, as compared to January 1, 1929 to December 31, 1929·

Cocomalt for...

CONVALESCENTS—The high caloric value and quick assimilability of Cocomalt makes it an especially valuable food for convalescents

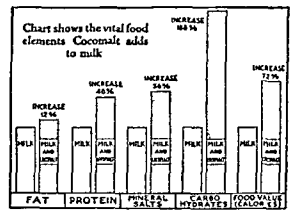
GENERAL DEBILITY—The necessity for a concentrated food of high digestibility in asthenic conditions is met by Cocomalt.

MALNUTRITION—Undernourished children and adults respond splendidly to the balanced ration of Cocomalt mixed with milk Furthermore, it increases the appetite.

TUBERCULOSIS—Cocomalt is very useful in increasing the caloric value of tubercular diets without throwing an additional strain upon the digestive system Its mineral content is likewise useful in producing calcification of tubercular lesions

POST OPERATIVE—Following an operation, Cocomalt meets the demand for a highly nutritious food that does not produce intestinal fermentation or stasis

FEVER CASES—The high carbohydrate content and caloric value of Cocomalt make it extremely valuable in treating fever cases. It saves body proteins



EXPECTANT MOTHERS—During pregnancy, Cocomalt answers the great need for Vitamins B and D Provides the additional food needed by the developing foetus

NURSING MOTHERS—Cocomalt provides necessary food elements for the production of milk, without inducing constipation.

Cocomalt—the delicious food drink—adds 70% to the caloric value of milk

COD LIVER OIL

Vitamin-tested
Vitamin-protected

LOFOTEN—Norway—north of the Arctic Circle is the source from which comes every drop of Puretest Cod Liver Oil.

Only the cod which are caught during January, February and the first week in March are used, for this is the season when the livers are richest in vitamins; the fish having recently spawned and then gorged themselves with the vitamin-rich algae which is prevalent in the Lofoten waters.

As the temperature is around freezing, and only twelve hours elapse between catching and landing the fish, the livers reach the factory in perfect condition.

To maintain the uniform medical potency of Puretest Cod Liver Oil, beginning at its source it is subjected to the rigid control of Professor E. Poulsson, director of the Pharmacological Department of the University of Oslo.

The purpose of the scientific investigation of the vitamin content of Cod Liver Oil is not merely to establish the presence of vitamins, but to determine the quantities in which they occur—to find a measure for the activity of the oil.

Professor Poulsson's tests of Puretest Cod Liver Oil show that it has a Vitamin A content of not less than 50,000 U.S.P. units and a Vitamin D content of not less than 13,333 Oslo units in each 100 grams.

This information is not only the result of Professor Poulsson's investigation at the source of supply, but proved by such an authority as Dr. Charles W. Hooper of the H. A. Metz Laboratories.

Puretest Cod Liver Oil is usually imported in batches of approximately one thousand barrels to a shipment. Protected from deterioration by inert nitrogen gas. A certified biological analysis accompanies each shipment.

Upon receipt of a shipment from Norway, each barrel is inspected and tested by our own Analytical and Research Department and no oil is used that does not merit the high quality standards of the United Drug Company.

Puretest Cod Liver Oil may be obtained in any Rexall or Liggett Drug Store. We will be glad to provide any further information desired by the Medical profession regarding Puretest Cod Liver Oil. Physicians are invited to ask for samples for clinical test.

DUNKLIN COUNTY MEDICAL SOCIETY, MISSOURI

The following description of the meetings of the Dunklin County Medical Society contained in the March issue of the Journal of the Missouri State Association shows what a small medical society can do when it assumes the leadership in medical civics:

"During the year 1929, the Dunklin County Medical Society met seven times with an average of ten doctors present at each meeting. Fifteen members were in good standing with dues paid in full. Five were made Honor Members (worthy physicians of 70 or more years). Scientific programs were not planned, leaving these for the Five County Group, but round table discussions concerning many phases of medical practice were held. Many plans were discussed throughout the year, among the most important being: Cooperating with the county health unit to immunize against typhoid and diphtheria; a method for better collections of accounts which resulted in the organization of the Dunklin County Physicians Business Association; discussion of the building of a Dunklin County Hospital. One new member, Dr. Wheeler Davis Kennett, was added to our membership.

Meetings During 1930.—Dr. S. E. Mitchell, who served as President for 1929 was reelected for 1930 because of his splendid leadership. Eight meetings were held throughout the year with an average of nine members present. Each member was designated a committee of one to study and report on some problem concerning a county hospital. Eight members responded with splendid studies and information on the following: The legal manner of obtaining, maintenance, number of beds needed in a county of 40,000, expense of running, needed help, needed equipment, how to run it, and proper executive help. While a great deal was accomplished in gaining valuable information we realize with existent conditions it is not time to start a hospital. In the near future we are certain our dreams will be fulfilled."

LEGISLATIVE METHODS IN COLORADO

Legislation in Colorado is in the hands of the Public Policy committee, whose method of procedure is described in the March number of *Colorado Medicine,* as follows:

"Members of the State Society who possibly have thought it too much trouble to write the one or two letters to legislators requested by the Public Policy Committee would do well to consider the time being devoted to this work by the Committee members. Scarcely a day has passed that one of more members have not attended the legislative sessions at the Statehouse. The State

(*Continued on page* 513—*adv. xxv*)

(*Continued from page 512—adv. xxiv*)

Society and its work have been put ahead of private practice, business and pleasure.

"In support of our legislative program pamphlet material has been prepared, quickly printed, and placed in the hands of legislators Other material, suddenly needed, has been obtained from the American Medical Association's Bureau of Legal Medicine, sometimes by telegraph or long distance.

"Co-operation of other organizations, medical, public health, and lay, has been solicited and in several cases obtained. Our own Woman's Auxiliary has co-operated through its officers and is still at work.

"Far from being limited by the legislative program advocated by the House of Delegates, the work of the Committee has of necessity been for the most part devoted to other legislation Forty-two bills were introduced in the legislature relating to medical affairs and public health, of which only six constitute the program sponsored by our Society. All of these bills had to be studied, compared with existing laws, investigated for the ever-present 'jokers,' be evaluated. Attorneys, departments of the State government, other organizations, had to be consulted before decisions were made.

"Each member of the Committee has had the doubtful honor of being formally registered as a 'lobbyist' in the legislative records. Denver members have spent many hours appearing at meetings of House and Senate committees, or sitting on the sidelines explaining to individual legislators the merits or demerits of this bill or that

"This can give but a sketchy idea of what it means to be a member of the Committee on Public Policy, especially to be a member residing in Denver and thus close to the scene of action. If it impresses those who read it with a slight conception of what the medical profession and public health in Colorado owe to this group of doctors, it has accomplished its purpose."

MEDICAL HISTORY OF TEXAS

The February issue of the *Texas State Journal* contains the following editorial note on a medical history of Texas, written by a member of the Woman's Auxiliary:

"A Medical History of Texas has at last been published. The author is 'George Plunket Red' known to her close friends by that name, but to most of our readers as Mrs. S. C. Red, the distinguished wife of our beloved and also distinguished ex-president, Dr. S. C. Red of Houston. The book comprises 344 pages of reading matter, and numerous illustrations It sells at $3.00 and is worth every cent of it. The profits from the sale of the book for the first two years

CULTISTS AND HOSPITAL STAFFS IN WASHINGTON

Northwest Medicine for March has the following editorial on the application of chiropractors to be allowed to treat patients in a public hospital in Seattle:

"Whenever a public hospital is constructed and opend for the reception of patients, there ensues a clamor on the part of various irregular practitioners and their adherents for the opportunity of treating patients in accordance with their peculiar tenets and practices. This has recently been illustrated in connection with opening Harborview Hospital at Seattle. Chiropractors and drugless healers united in a vociferous demand that a portion of the hospital be set aside for their use in the treatment of patients. The county commissioners gave a public hearing, at which the reasons for such privilege were presented, with statements to the contrary by representatives from the medical profession. These petitioners and their supporters claimed the right of utilizing this public institution, since otherwise they are being taxed without representation. Some of the medical speakers stated they had no quarrel with these irregulars as to their methods of procedure, but called attention of the commissioners to the fact that the hospital could not be rated according to the standards of the American College of Surgeons, if these irregular practitioners were permitted to participate in the treatment of patients. Neither would interns nor nurses consent to serve under the direction of any except regularly educated physicians and surgeons. In due time the board of county commissioners announced their decision against permitting these irregulars to practice in the hospital, giving as their reason the above mentioned objections."

17. Future Position of Medicine.

To the House of Delegates:

Gentlemen:

The President has the pleasure of submitting a report of the year's work.

Two hundred and three medical meetings, including conferences and committee meetings, have been attended as follows:

Eight meetings in District Branches.

Thirty-two meetings in County Societies.

Four meetings in Academies of Medicine.

Six meetings in the States of Illinois, Texas, Pennsylvania, New Jersey, Massachusetts, and Maryland.

Forty-one special meetings.

At these meetings ninety-one prepared addresses have been made on features of medical problems, relationships, or obligations.

Some part has been taken in the discussion of one hundred twelve conferences and committee meetings. A few standing committee meetings have not been attended because of conflicting dates.

The distance traveled is approximately forty thousand miles.

One thousand five hundred and twelve personal letters on the work of the year have been answered.

Twenty-eight medical articles have been published and twenty-seven pages of editorial comment have been writen for the Journal.

The President has provided his own secretarial help.

As a member of the Governor's unofficial Health Commission, your President has attended eight regular sessions and four sessions of the sub-committee on Medical Care and Medical Service, of which he is the chairman. The report of this committee has not yet been made.

As a member of the Governor's Committee to Review Medical and Hospital Problems in Connection with Workmen's Compensation, your President has attended the three sessions held and one session of the sub-committee on Medical Problems. The sub-committee is made up of nine members, six of whom are members of organized medicine.

It is obvious that the office of President of the State Society has come to be a full time task.

A condensed report is submitted with the Recommendations and an accompanying booklet of seventeen sections, indexed for your convenience, should you desire to consult it. This booklet sets forth in detail a discussion of the observation of the year. The study of the problems of medicine was approached without theory, and out of the year's experience has come a degree of unexpected orientation, in the main commendatory of the profession of medicine as the greatest factor in human welfare and human service.

Present-day Principles of the State Society: These were foreshadowed and used in meeting professional problems arising in the different stages of social evolution from the beginning of the State Society.

There were difficulties even from the beginning in securing enactments of laws. I have not learned of any that had unanimous support until after their enactment.

The problems are greater today only because of greater social changes and complexities of society resulting in greater health and sickness problems involving both medical care and medical service. The profession of medicine has greater problems only because of these changes which are are also common to every field of human effort.

The layman has little interest in organized medicine. He is interested in the services of medicine.

Many sections of the State have solved their own problems of health service and medical care and medical service on a basis of community interest and community support. Some counties seem to have done this because they have made use of official and unofficial agencies in their scheme of things under the technical leadership of medicine. In these counties organized medicine seems to have advanced just as it built new pathways of public service, made contacts with public interests, and established working relationships with them.

There have been difficulties in the past relatively as great as today. Medical statesmanship straightened them out.

The present problems are not the science of medicine, but the relationships of medicine. Medicine's responsibility for public problems will be easily met if there is a partnership understanding between the public and medicine.

If common sense is the "bedrock of medicine" as well as "of law," I am sure that from all that I have observed this year that it can be a mighty factor in the solution of medical problems, if it is backed by community perspective and if the doctor has a vision of the needs of his community.

Two forces—common sense and statesmanship.

I suggest that every doctor read and digest as opportunity offers the one hundred twenty-five year history of organized medicine as a background for the consideration of present day problems. It is proper for the profession to think through these problems as promptly as possible and then be guided by whatever adjustment of relationships is found necessary. No one can raise false issues. Whatever the facts are will determine the issues.

The Journal: The Journal is designed and maintained in order to reflect all the activities of the State Society and to give a résumé of the trend of medical public opinion.

It is not practicable for the Journal to have a reporter attend all the meetings, conferences, and committees. The Journal must, therefore, depend upon voluntary reports from the officers and committeemen.

Bulletins have been sent out this year to county societies by the Public Relations and Economic Committees on special topics of current importance.

Popular medical publicity has been handled by the State Department of Health. Its press releases and radio broadcasts are fully up to the standards of several State societies which give special attention to these forms of publicity. The President recommends:

1. That the officers and committeemen be expected to assume responsibility for reporting to the Journal the results of meetings and their activities.

2. That the Journal request the chairman of every committee or the leading physicians in various activities occurring throughout the State before any known meeting or if not, as soon as possible thereafter, to make a statement for the Journal of what transpired.

3. That the sending of bulletins to the officers of the county societies be approved, when in the judgment of the committees it is necessary.

4. That the popular medical publicity now handled by the State Department of Health be approved and the Department be requested to continue.

Graduate Education: This activity of the State Society is one of the most valuable ones. It is steadily bringing modern treatment of disease within the scope of the general practitioner of medicine and enabling him to apply it to the patient without subjecting the patient to the expense of a specialist.

It is quite possible that this activity of the State Society may soon be followed by some plan which will more effectively reach each individual physician. It is easy to bring instruction to all those who will attend the lectures. The evolution of sentiment for graduate education may soon bring into greater cooperation the teaching of the medical schools.

I recommend that the subject of graduate education be given most careful consideration with the object of expanding it to the fullest practical limit.

Economics: Economics naturally follow Graduate education.

Competent medical service, medical care, and the preventive practice in general will be followed by increased economic rewards.

The Committee on Economics has gone to the heart of difficulties that have existed a long time between physicians doing compensation work and the insurance carriers. The proposals in the report of the committee regarding the principles of

basic fees need not be considered as a fee list endorsed by the State Society but as an agreement between each county society and the insurance carriers, as the county society decides. As a profession we must see with a clear perspective and use the necessary degree of statesmanship to devise workable methods of solving present day problems.

I recommend that the report of the Economic Committee be carefully read and digested so that the proposed principles of relationship may be understood and from this beginning strengthened as needed and deficiencies filled in as required.

Public Relations: No activity of the State Society is doing more for medicine in this State than public relations. It is one of the most vital forces in medicine today. Its value is obvious and, more than that, there flows from it an intangible influence that will extend on and on, steadily building up a new professional attitude toward the value of a spirit of conference and cooperation with other health influences as a means of meeting public medical needs.

I have observed this in many parts of the State this year and have heard many groups of physicians discuss the evidence of the excellent work done by this committee. There is a growing interest in public relations outside of New York State. The public relations work in this State is being recognized as an epoch making force to bring the medical profession into the leadership that belongs to it naturally.

There is a rising tide of interest. Physicians are beginning to see that practice can become more prosperous by cooperation with the objectives of sound programs sponsored by other organizations. There is no better example than the work that the family physician may do for school and preschool children. He is the competent physician for this work because of his knowledge of the physical or mental handicaps and the environment of these children. Aside from the real service to public health, this work is of striking economic value to the general practitioner in each county of the State where it has been carried out.

The work of the Public Relations Committee has been on new ground. Its accomplishments have grown each year and just in proportion to the development of leadership. Leadership must possess intimate knowledge of organized medicine and the needs of the family physician. The leadership stimulated by the Public Relations Committee has kept medicine in closer touch with the public at large. The inter-relationship of the profession, health departments, other departments of the State government having health interests, school hygiene and health service, industrial hygiene, and general medical problems arising from the present day changes in all relationships have had close attention by the Public Relations Committee this year.

I recommend that ample financial support be given the Public Relations Committee for its enlarged plans for the coming year.

The Metropolitan Area: Conditions confronting the profession are superficially different in the metropolitan area than in the rest of the State. Closer study indicates, however, that the deeper problems confronting medicine are the same all over the State. The greatest difference in the two areas is the density of population.

The Public Relations Committee has more largely worked outside of New York City than in the metropolitan area. This year for the first time more effort is being given to the problems of relationships. Greater New York and a greater effort is being made to build into one organization the means of meeting professional problems in a densely populated urban area and the less densely populated cities and the rural areas of the State.

To meet the social complexities of medical relationships in Greater New York is a huge task. It can only be done by organization. Such an organization should be tied closely with the entire body of organized medicine in the State so that any conclusions reached may have the force of the entire profession of the State.

The time is near when increased facilities must be had for the purpose of efficiently carrying on this work in the city and in the State. It probably means increased secretarial help and it may mean an executive secretary. We are not yet quite at this point, but the indications are rather plain of its need. Committees can make the study, can formulate conclusions, but it is beyond the capacity of any doctor to give the necessary time to interpreting medicine's position in public affairs. All this simply indicates the need of a business medical organization.

The District Branches: The District Branch President occupies a midway position between the State Society and the County Society. In reality he functions in several capacities. He is a member of the Council, the House of Delegates, and the Board of Censors of the State Society. It is his duty to visit each county society in his district and aid it in its work. It is his duty to organize and conduct the business of the District Branch.

The State Society's chief interest at the present time is that the county societies should make the fullest use of the services offered to them so that the individual physician may develop scientifically and extend his usefulness in the community as an aid and director in public health work. Since the Branch presidents do not all realize the importance of their taking an active interest in the county society's development, the State Society should devise a plan of assisting

the Branch presidents to realize their responsibility. The most practical way that I know of is by conference with the officers of the State Society in the beginning of the yearly administrations.

An outline of what should be done in this conference might be something like the following.

1. Plans for increasing membership in county societies.
2. To consider the time, month, and hour of county society meetings.
3. Each county should have a regular and, therefore, expected place of meeting.
4. The Branch president should interest himself in the program of the county society.
5. Even the kind of notice sent out for the meeting is important in attracting an attendance.
6. Every District Branch should have regular standing committees and their reports should be expected and called for at each regular meeting.
7. The committees should correspond to those of the State Society and the chairman of each should be a member of the corresponding State Society committee.
8. The annual meeting of the District Branch is its one activity which is definitely established, and the value of its scientific program is proven by the records, which show that more physicians attended the annual meetings of the District Branches last year than attended the annual meeting of the State Society. The District Branch presidents are beginning to realize that the annual meeting affords an opportunity for the discussion of other subjects than purely scientific ones; as, for example, the economic conditions of the District, the public health activities, activities of welfare and voluntary agencies, as well as the welfare of the component county societies. This idea will admit of considerable development, and in order that the greatest advantage may be gotten from the development of such program, consideration should be given by the presidents, in conference, to such subjects as might arise under these general heads. Men should be chosen as officers of the District Branch who are able and willing to devote much of their time to the duties of their offices. The State Society, as a State organization, must for its own protection, develop the strength of its subsidiary organizations, and that will require time and personal effort on the part of the officers. This should be impressed upon the societies when they are electing their officers. Four District Branches will elect officers this year and the retiring president should lay emphasis on the necessity for selecting a successor who can perform these services to his District Branch and to the State Society.
9. While the duties of a District Branch President are defined in our constitution, yet, nevertheless, certain men have occupied the position for the two years without having discovered in that time what their duties were. It would, therefore, seem that in order that the State Society might get from them the greatest degree of cooperation, it should annually discuss with the Presidents the nature of these duties.

To sum up this subject, the duties of the president of the District Branch are the obligations, responsibilities, and opportunities as a member of the Council, House of Delegates, Board of Censors, and the administrative head of all the functions of a District Branch.

The district Branches have undeveloped potential resources which, if properly employed, would greatly enhance the usefulness of the State Society.

I recommend that a conference of the District Branch Presidents and Secretaries, the Executive Officer, President, and President-Elect of the State Society be held at the beginning of the year's work for the purpose of discussing the responsibilities and opportunities of the District Branch Presidents.

Public Health: Protection of the public health has always been the concern of nations. It has always been the concern of New York State. Laws have been enacted from time to time since 1850 just as health needs required and just as scientific medical knowledge developed for the prevention of disease, and just as methods of administration and practice advanced. All the various laws were mandatory and were accepted by the medical profession as sound procedures to meet existing conditions at the time of the enactment of each of them.

The protection of the public health we all endorse and strive to promote, but we must not confuse that with the practice of medicine by the public. Both activities are frequently embraced under the general term public health.

I believe that we all see that the practice of medicine is in a state of active transition. It is equally true that the relationship of medicine to public health practice is in a state of active transition due to changing health needs, increased knowledge of how to prevent disease, and new methods of public health practice.

If it is true that the greater the mind of man, the more he seeks for truth uninfluenced by lesser things, then the profession of medicine in New York State—a body of educated men—should lay aside justified reactions to past occurrences as guides in thinking out the next forward step in public health organization in the light of present knowledge and present public health practice. Medicine must decide whether this is in the interest of the public and in the interest of the profession of medicine.

County health legislation is no more a public health issue than it is a medical issue. Some county societies have taken a position this year which is not one of opposition to a definite plan as much as it is opposition to any plan to improve health administration.

Some constructive policy must be adopted. The need for improvement is beyond doubt. The only question is as to the plan by which this can be accomplished.

I am told by the leaders and officers of the Sanitary Officers' Association that they desire to support any plan reached after due deliberation with other interested groups and that they will advocate any plan reached in this way that seems expedient to secure the passage of legislation at the next session of the Legislature.

I recommend that the State Society determine its policy toward organization for administration of public health in the light of the present development of scientific knowledge and the present knowledge of public health practice for the prevention of disease. I believe that it is the obligation of medicine to take a constructive position on this question and thereby show its leadership in public health affairs.

Special Health Commission: A Special Health Commission was appointed by Governor Franklin D. Roosevelt on May 1, 1930, to study and report to him upon the administrative and legislative aspects of public health in the State and to examine the extent to which the needs of the people of the State were being met in the field of public health in order that existing scientific knowledge may be better utilized. The Commission was made up of fourteen people and given power to enlarge its personnel by sub-committees. As finally organized it consisted of eighty-six people, fifty-three of whom were doctors and the rest made up of health experts, representatives of voluntary health and civic associations, and every department of the State government having health interests.

The Commission investigated and studied the problems assigned to it for ten months.

The Commission made twelve major recommendations under the general headings of county boards of health; local health administration; tuberculosis; venereal diseases; cancer; maternity, infancy, and child hygiene; public health nursing; crippled children; industrial hygiene; public water supplies; stream pollution and public health personnel.

The Commission made its report to the Governor on February 18, 1931. A bill was later introduced in the Legislature for the promotion of public health at the desire of the Governor of the State.

The Public Welfare Law: In all counties in which this law is functioning properly in meeting its social problems and in paying the physicians for medical services, it is largely due to the cooperation of the county society through its Economic or Public Relations Committee with the Commissioner of Public Welfare. In only a few counties of the state is the law fully serving its intended purpose. It deserves to be more widely administered because of its service to the indigent and its effect on the economic rewards of medical practice.

I recommend that each county society consult any one of the few counties in which the purpose of the law has been established. It should by this time be distributing its benefits in every county of the state.

A Committee on Activities: Throughout the year I have been impressed with the need of some method of coordinating the work undertaken by the standing and special committees. Each one works too independently for the best results. Each one may miss an inspiration that might come if he knew "what the other fellow was doing." The thought has often occurred during the year that there should be some method devised to coordinate activities, to prevent overlapping, and to fill in the deficiencies.

Early in the year I called the chairmen of all the committees together for a conference, asking them to prepare a concise report of their plans, and after that the meeting was continued as a conference on activities. This conference was well attended. It resulted, of course, in a better understanding of the work of all the committees, but it was not enough and should have been followed up by several other conferences during the year. The work of the President, however, was too time-consuming for him single handed to keep this bit of organization going on.

Continued observation during the year indicates that it would be of very great value for many reasons to have a Committee on Activities. It would first of all provide for an understanding of the work as a whole and a means for determining the values of what we are doing. In a sense, it would afford an opportunity for a real appraisal. It could determine whether we are getting our money's worth and what further things could be done in the interest of the medical profession.

I would, therefore, suggest that the chairmen of the standing committees be designated as a Committee on Activities and brought together several times during the year for the purpose of reviewing their plans and programs.

The Trustees: I believe the Trustees are hungry for more to do. Their work is too limited to keep them interested. They are experienced and trained men because of having already served the Society in other important ways. I believe that new machinery should not be installed until existing machinery is used to capacity. This is a sound principle in industry and it is just as applicable to medical organization as it is to industry.

I, therefore, recommend that the monthly reports submitted by the chairmen of the various standing and special committees be duplicated and sent to each trustee. As a body they have the

responsibility of the care of our funds and are called upon to make appropriations adequate for the activities outlined by the Executive Committee and the standing committees and it seems only reasonable to me that they should have frequent reports from the standing and special committees, as they now have from the Executive Committee, in order that they may be properly oriented with regard to the Society's activities and the use to which the funds appropriated by them are placed.

Organization: The profession is properly, relatively independent and individualistic in scientific medicine, in medical research, and in the individual practice of medicine. In its relationships to hospitals, to health organizations, to all departments of the state government having health interests, it should exert its influence and support its policy after reaching a conclusion by unanimous support by every component county society, if its influence is to be effective.

Though organized medicine is a representative body, reaching its conclusions in the House of Delegates, representing as it does the component parts of the State Society, medicine too frequently undertakes to express its opinion independently of its own organization. Majority opinion seems to be accepted often with mental reservation.

Organized medicine welcomes minority opinion within its own Councils. When a conclusion is reached, it should be the opinion of medicine in deciding a medical policy. If we are ever going to have an organization that will be effective in maintaining medicine's position in the solution of the great public problems of medicine, we, as an organization, must have a policy which, when agreed upon, will have unanimous support.

I want to urge every doctor to help to make his county society a better organization in order to meet professional problems here now and which at any time may become more active if the government undertakes to exercise its parental function in order to meet the social problems of adequate health and sickness service. Medicine must be in a position to maintain a desirable relationship in public problems.

Since the organized profession is the most competent body to consider technical medical problems, medicine should offer plans for their solution. If they are public problems, proposals should be made to the agency that can carry them out or to the state in any of its plans to meet its responsibilities for the health of its dependent citizens. An example is the rehabilitation of crippled children.

Organized medicine, as a whole, does not seem to take seriously some problems of wide importance, or if aware of them, medicine is neglecting to assist in their solution. Some of these problems are the distribution of physicians, splitting fees, costs of medical care, educational standards of specialism. It is all a difficult piece of work. To carry on constructively the routine established by highly interested pioneer work requires more enthusiasm than can be commonly expected. With the exception of fighting tuberculosis, physicians receive practically no assistance from either official or unofficial agencies.

On the other hand, there are many practical examples in the state of the local profession constructively meeting the problems of health and sickness service. I have no doubt that it will become more general. We need better organization to meet effectually the increasingly complex problems of the present day. The situation in medicine over the state in regard to its relationship to public problems is a mixed one.

Some counties are guided by tradition. Some consider the changing needs of society. Some consider scientific medicine the whole problem. Some consider a cooperative relationship to other organizations essential in meeting the complex medical problems of modern society.

Medicine ought to be as well organized as other interests which could be cited as illustrations, when it has to deal with public problems.

Under "The District Branch," organization is further discussed and recommendations made.

Medical Care and Medical Service: Physicians should consider the public interest and discussion regarding medical care. Medical care and medical service should not be confused. Medical care pertains to nursing, hospitals, and their equipment. Medical service pertains to that which a physician renders.

It must be obvious to most physicians that the general subject of medical care has aroused more and more interest during the last decade and especially in the last two years. Physicians should consider this public interest and criticism and what constitutes adequate medical care and medical service.

Aside from standards of medical service, I would like to bring to the profession of the state the question, is it available to all the people, and if it is not, how can it be made available? The problem of the availability of medical service lies between the well-to-do who have no financial problem and those taken care of by the Public Welfare Law. What will make medical care available to this class?

It is a public calamity if physicians cannot be paid for their services as other citizens are for their services. Sooner or later professional service will suffer. The questions of medical care and medical service are large ones. Many facts are already at hand. The interpretation and solution are the next steps.

I recommend that either a special committee be appointed to make this interpretation or that the duty be assigned to the Public Relations Committee and that it study three main questions. What is adequate medical service? How can it

be provided for all the people? How can such service be adequately paid for?

Appraisals: The discussion in this section is intended to stimulate thought regarding the public appraisal of the adequacy of the services of medicine.

Industries are constantly making appraisals of the health and sickness problems of their people from an economic point of view.

There is a discussion by various interests and individuals of sickness insurance. Should medicine think out for the hazard of illness whether better service can be rendered under an insurance plan than by the present plan? Would it be better for medicine to make some study of how the profession could render better service and be paid for its work by those whose incomes are not far enough above the necessities of life to pay for adequate service themselves? There is an obligation on medicine to lead in improved methods of caring for the sick.

The relationship of medicine to all health interests should be carefully considered. What is medicine's interest in health administration, medical care, medical service, and providing better service? What is medicine's interest in cooperation with official and unofficial health agencies? What is medicine's reaction to the magazine and newspaper stories regarding the adequacy of health service?

Any appraisal of our own resources is for our own use and not for the public, and only for the purpose of making proposals for the solution of medical problems.

I recommend that a resolution be presented to the American Medical Association at its 1931 meeting requesting that a commission be appointed to make a study of the relationships of medicine to the public, to medical care, to medical service, and to all the interests of public health administration and practice for the purpose of developing constructive thought regarding them under the leadership of medicine and that this Commission be asked to make a preliminary report with such recommendations as it may have at the 1932 meeting of the American Medical Association with the object of bringing the influence of the organized medical profession to bear on every medical problem.

Future Position of Medicine: If the vision of medical relationships for the future has been enlarged and brought a little nearer to every-day thought, this administration will have accomplished one of the things that it set out to do. There are still problems to be solved, but the evidences of an increasing statesmanlike attitude toward them, showing here and there all over the state, prompts one to believe that there is just ahead a certainty that the greatness of the profession of medicine still lives.

The future position of medicine will rise or fall largely by its relation to the state of public opinion regarding the great problems of health and sickness service and professional attitude toward their solution and toward cooperation with other agencies with resources to meet public medical care arising from the present day rapid social evolution. Sooner or later public opinion will make decisions regarding better administration of public health and increased availability of adequate medical care and medical service. The profession of medicine should do this first. The public expects the medical profession to do it.

If medicine would survey itself and its public relationships as a whole, it would help the profession to have a better understanding of the situation in medicine than if the problems of medicine are considered separately. Single problems can easily be distorted or seen out of proportion. The truth will only be seen by taking all these things together.

I have undertaken to summarize as well as time and space permit the medical activities that have been carried on by organized medicine this year. I have undertaken to make the condensed report as comprehensive as possible.

My opinion is that present-day medical attitudes are sound. There is a growing understanding that cooperation of all health influences is a sound procedure. There is a new and growing spirit of cooperation and a new sense of civic consciousness on the part of the profession of public officials, and the people whom they represent in health matters, but this is no more conspicuous than that there is a new attitude in medicine. It is true in this state, and I have seen evidence enough to be sure that it is growing in other states.

While I have commented at some length on the work of the Committees on Public Relations, Economics and Public Health and Medical Education, I am sensible of the excellent, constructive and enthusiastic work of the Scientific, Physical Therapy, Medical Research, Periodic Health, Insurance, and Legislative Committees. Their reports will tell the story.

I wish to express my appreciation of the excellent work done this year by the officers, editors, and standing committees. A greater volume of work has been undertaken and carried through this year. Nearly every committee has advanced into new fields. In every activity there has been obvious results, and the intangible influences will continue to run on and on.

The greatest hope that I can express is that someone in each field of activity will carry on and give the leadership necessary to adjust medical relationship to new conditions.

Respectfully submitted,

WILLIAM H. ROSS, *President.*

April 15, 1931.

REPORT OF THE SECRETARY

To the House of Delegates.

Gentlemen:

Your Secretary again has the honor of presenting an annual report. When six years ago he assumed the duties of the office he had no idea of the extent and magnitude to which his burdens would grow. The days of a perfunctory secretaryship have passed and consequently he renders his report in the dual capacity of a Secretary and an Administrative Executive.

THE SOCIETY

During these six years the Secretary has had the pleasure of reporting a gradual, steady and healthy growth of the Society both in membership and activities, with a consequent and corresponding growth in the influence that it has been able to exert and the importance of the position that it has been able to attain in all matters pertaining to the health and welfare of the public. Interest has continued and enthusiasm has grown to such an extent that it has become in many instances individualistic and therefore threatening to the welfare of the whole.

The amount of work done by the officers and various committeemen has been tremendous. Few can conceive of how much time and thought have been consumed in upholding the dignity, promoting the welfare and forcing proper recognition of the profession and of organized medicine.

In all this earnestness and enthusiasm we must not lose sight of the fact that on account of the various activities there has been created within the organization many subsidiary bodies with separate specific duties and that, as the engine needs the governor, so each and all of these of necessity require the control of a coordinating power, a body of centralized authority. Without such, the work would become a heterogeneous mass of individual thought and action and all power and influence be lost. For this reason the idea of an Executive Committee was conceived.

Over-enthusiasm is even more dangerous than lack of it; for lack may be supplied, while over-enthusiasm frequently rushes in tumultuous haste past important points, fails to perfectly analyze situations and does not pause to consider the viewpoint of others; thus failing to absorb thought and wisdom and broaden its own vision. It therefore reasons from erroneous or false premises and reaches conclusions based almost entirely upon personal or individual opinions which are often unreasonable, untenable and unsatisfactory to the body as a whole.

By individual is meant not only an individual person but also a group, committee or any component of an organization or family. Individualism has no place in the body politic, economic or social. These are parlous times and the general feeling of depression and unrest is felt even in medical circles. If opposition and oppression threaten, they must be met with a united front; harmony should be the watchword, harmony and solidarity within and militant aggressiveness without. Internal dissension, pessimism or dread of the future has no place in the organization. Even the appearance of a house divided against itself gives courage to the proponents of adverse legislation as was seen in the last hours of the legislature.

Economic problems are confronting all conditions of society and business and the medical profession has not escaped. It behooves organized medicine therefore to carefully consider and study those that particularly affect the profession and endeavor to influence its members to work together for the common-weal, casting aside all consideration of personal aggrandisement, financial or otherwise, and by word and action, by constructive criticism, and moral support uphold the hands of those they have selected as leaders.

THE SOCIETY'S OFFICES

For the purpose of properly conducting the administrative and business end of its affairs, the Society maintains three offices; the Legislative Bureau at 100 State Street, Albany; the Publication offices on the fifth floor of the Academy of Medicine Building, New York City; and the general administrative offices on the fourth floor of the same building.

Although these offices are not overmanned and the salaries of the personnel in some instances do not quite compare with those performing similar duties in the business world, the work runs smoothly and efficiently. Each employee is more or less a specialist in her line and has to be possessed of intelligence and initiative. Those in the publication offices are sub-editors and Miss Briggs, the secretary-stenographer, in the Legislative Bureau acts as stenographer reporter at all conferences and assists in the registration work at the Annual Meeting. The thanks of the Society are due her not only for her work but for her never-failing courtesy and willingness to assist whenever called upon.

Of the work of the Publication and Legislative offices, the Secretary can speak advisedly for although not under his personal direction, his duties compel him to keep in close touch with them.

Of his own immediate staff, the only comment he can make is that a more cheerful, courteous, willing and efficient office staff does not exist. The Secretary takes pleasure in extending to them and the Manager, Miss L. D. Baldwin, his sincere thanks and appreciation.

For thirty years Miss Baldwin has served the Society faithfully and efficiently. Her fund of knowledge and her intimate touch with all details of the work have been, and are, of incalculable value.

Mrs. Roetger, the Assistant Manager, has served the Society ably for twenty years.

FINANCIAL DEPARTMENT

It is almost unnecessary to call attention to the sound basis upon which the finances of the Society are founded and to the safe and sane policies of the Board of Trustees. The reports of the Board and of the Treasurer speak for themselves.

The Society is indeed to be congratulated upon having in charge of its finances men of such high integrity, of such loyalty to the organization and of such excellent business qualities as the Treasurer and the gentlemen who form the Board. Sitting as Secretary of the Board, but without voice or vote, and being Secretary of the Business Committee, the Secretary of the Society has excellent opportunity to see and judge and makes this statement advisedly and without reservation.

There has been from time to time in the minds of newly elected committeemen and councillors, a confused idea as to the manner in which appropriations are handled, some of them appearing to think that appropriations could be paid in bulk. This, however, cannot be and never is done. An individual bill for each item of expenditure has to be rendered and is charged against the appropriation. Payments are made by voucher checks, the voucher being initialed by the Manager and the check signed by the Treasurer and countersigned by the Secretary. In this way, the interests of the Society are thoroughly safeguarded and there can be no error or looseness of expenditure.

LEGAL DEPARTMENT

When a year ago, Mr. Lorenz J. Brosnan took up as Counsel the work laid down by Mr. Lloyd P. Stryker, he was already well-known for the excellent manner in which he had conducted many of the trial cases. This excellence of work has continued and many letters of thanks and commendation have been received by the Secretary from those whom he has defended.

The members of the House will remember that Mr. Brosnan introduced as his assistant, Mr. Maxwell C. Klatt, whose personal presence and the short address he made very favorably impressed the Delegates. But a few short weeks passed when the sorrowful news of his sudden death was received. His place has been taken by Mr. Thomas H. Clearwater whom the Delegates will have the pleasure of meeting this session.

Despite the fact that the membership has been notified repeatedly that the Counsel is retained in an advisory capacity for the legislative and administrative bodies of the Society and that it is neither legal nor right that he should be expected to render opinions to others, he continues to receive numerous letters which he has to refer to the Executive Committee before answering. Attention is again called to the following resolution:

"All questions or requests for information by committees, county societies or individuals must be referred therefore through the Secretary's office to the Executive Committee with which Counsel sits."

The Secretary acknowledges with thanks his indebtedness to the Counsel for many acts of kindness and for his valuable advice in conducting certain phases of the Society's correspondence.

COMMITTEES

The work of the committees, both standing and special, has been excellent in every way and when one considers the character and amount of work done by these men, holding frequent meetings and coming from widely separated districts, too much cannot be said in praise of their loyalty to the interests of the Society and their endeavors to benefit the profession.

The Secretary voices the appreciation of the Society and also extends his thanks to the Chairmen who have recognized his membership in the Standing Committees. He has not been able to accept all invitations but it is good to be remembered.

To make special mention of any one committee would be unjust; all have done their duty. Under the veteran leadership of Drs. Farmer, Sadlier, Bedell and Aranow, their respective committees have upheld the reputation of other years.

CONSTITUTION AND BY-LAWS

Experience teaches that the fewer and the more inflexible laws are the stronger and more effective is an organization. Nevertheless, a Constitution and By-Laws of three years' standing necessarily fail to meet changing conditions.

Our present laws were adopted in 1928 and a study of them shows many flaws and a need of being brought up to date.

Your Secretary therefore recommends the appointment of a committee to revise the Constitution and By-Laws to report at the next Annual Meeting in 1932. This committee to be composed of seven members, three of whom on account of their intimate knowledge of the needs and workings of the Society to be the President-Elect, the Speaker and the Secretary; the other four to be geographically distributed. The Secretary suggests that the House appoint such men as Drs. Ludlum of Kings, Rooney of Albany, Farmer of Syracuse and Trick of Erie.

The same reasoning that applies here applies also to the Principles of Professional Conduct and a Special Committee of the Executive Committee has endeavored to bring them into consonance with present ideas and conditions. The changes appear with the report of the Council.

As the Secretary was a member of this Committee it perhaps would not be proper for him to urge their adoption. He does, however, ask for them the careful consideration and study of the delegates.

EXECUTIVE COMMITTEE

The Executive Committee has held nine regular meetings, the May meeting coming too late to be included in this report.

The Committee organized at the meeting held in Rochester on June 3rd by electing William H. Ross, Chairman, and John A. Card, Vice-Chairman.

It was decided to hold regular monthly meetings in the Society's office, 2 East 103rd Street, New York City, on the second Thursday of each month.

In accordance with the authority delegated by the By-Laws the following appointments were made:

Publication Committee—Charles H. Goodrich, Chairman, Charles Gordon Heyd and Daniel S. Dougherty.

Editor-in-Chief—Orrin Sage Wightman.

Executive Editor—Frank Overton.

Budget Committee—John A. Card, Chairman, Charles Gordon Heyd and Daniel S. Dougherty.

Committee on Insurance—John A. Card and Charles Gordon Heyd.

Legal Counsel—Mr. Lorenz J. Brosnan.

The Executive Committee being essentially the business and administrative committee of the Society much of the business transacted during the year has been of a routine character such as the receiving and acting upon the reports of the committees and the Executive Officer; receiving and examining applications for the expenditure of funds not covered in the Budget and referring them to the Trustees with appropriate recommendations; appointing special temporary committees and providing for the proper carrying on of the business of the Society.

At its first meeting, it received the report of the Budget Committee which after examination and revision was submitted to the Trustees for final adoption.

The reporting of the entire transactions of the Committee would take up more space than can be afforded for the report and unnecessarily waste the time of the Delegates, mention will be made therefore only of those of general interest.

In accordance with the resolution of the House, the Executive Committee during the year remitted the dues of several members who from long-continued illness are temporarily disabled from continuing their practice.

The Committee ruled that members are entitled to have bills incurred for extra legal services in malpractice defense paid by the Society providing that such bills be presented through the Counsel's office as part of the legal expense.

Under date of September 11th, the following members were appointed a Special Committee on Cancer Prevention: Thomas P. Farmer, Chairman, James E. Sadlier, James N. Vander Veer, George F. Chandler, George W. Kosmak, Arthur W. Booth and Burton T. Simpson.

Under the same date the place and date of the Annual Meeting was set for June 1st, 2nd and 3rd, at Syracuse, and Dr. Frederick H. Flaherty was appointed Chairman of the Committee on Arrangements.

Mr. Thomas H. Clearwater was appointed attorney, vice Maxwell C. Klatt, deceased.

At the October meeting rules and regulations for the government of County and State Hospitals, recommended by the Public Relations Committee, were adopted.

The following members of the Committee on Arrangements were appointed: Frederick S. Wetherell, Wardner D. Ayer, Adelbert C. Abbott, Albert Getman, Albert E. Larkin, Francis J. Ryan, O. W. H. Mitchell and Thomas P. Farmer.

Under date of November 20th, the Standing and Special Committees were informed that all questions dealing with medical education must be referred to the Committee on Public Health and Medical Education and the President was authorized to prepare and send a statement to all the State Society Committees informing them of their duties and calling their attention to the fact that the Council and its Executive Committee are the authorized ad-interim executive and administrative bodies of the House of Delegates to whom all matters of importance, resolutions, etc., must be referred for approval.

The County Societies were instructed that the registration of physicians in the County Clerk's offices must be verified before election to membership and that transfers received from other component county societies must be accepted in accordance with Chapter 14 of the By-Laws.

Under date of January 8th, Drs. Card, Ross, Dougherty, Heyd and Goodrich were appointed a committee to examine and revise the Principles of Professional Conduct.

Under date of February 12th, the Governor was requested to give careful consideration to the advisability of appointing only representative physicians as members of the Public Health Council.

Under date of March 12th, the Committee on Legislation was informed that the Wicks-Hutchinson Bill should not be supported until certain amendments had been made.

Under date of April 9th, the Secretary's letter to the Niagara County Society regarding the Wicks-Hutchinson Bill was endorsed and the Secretary instructed to send a letter of like tenor to all the county societies and to publish it in the State Journal. Also to send a letter to all county societies stating that the endorsements of eleven ex-presidents were not endorsements of the Wicks-Hutchinson Bill but of the Governor's Special Health Commission.

The Report of the Committee on Medical Economics with the exception of the fee schedule and agreement was approved; these being left to

the individual action of the county societies.

It was decided to request the Governor to add Drs. Sadlier and Ludlum to his Committee on Medical Problems.

COMMITTEE ON PUBLICATION

Under the By-Laws the Executive Committee is charged with the duty of supervising the publication of the Journal and the Directory. This duty is delegated to a sub-committee on publication.

The Committee on Publication has held various meetings and conferences with the Editorial Staff and considerable business of importance has been transacted.

The Report on the Journal written for the Committee by the Executive Editor is here presented:

THE JOURNAL

The NEW YORK STATE JOURNAL OF MEDICINE is maintained as an official organ of the Medical Society of the State of New York, and contains the official announcements of the officers and committees of the Society and the records of their meetings. It also reflects the activities of the eight District Branches and the sixty constituent county societies, many of whom are constantly trying new experiments which develop into activities worthy of the adoption of the entire medical profession of the State.

Volume 30 of the Journal,—that for the year 1930, is the most satisfactory of all the volumes, because the activities of the State Society have been by far more numerous than ever before. Some officer or committee has had something of permanent importance to report in every issue of the Journal; and the department of "News Notes" constitutes a continuous record of current medical history being made by the Medical Society of the State of New York. This record is not merely of ephemeral value, but it constitutes real history which will be consulted in future years.

The State is not alone in the increasing field of activity of its Medical Society. Just as the State Society derives information from its constitutent county societies, so also does it profit by the records of the activities of other State societies as revealed in their State Journals. The department of our Journal called "Our Neighbors" contains items of increasing number and interest, because the societies of other States, like that of New York, are increasingly active in planning how the medical profession can fulfill its obligations to all the people throughout the Nation.

The increased activities of the State Society have imposed increased obligations on the editors and Publication Committee, and also upon the Executive Committee of the Council, on whom rests the ultimate obligations for the management of the Journal. Every week the editors have been compelled to consult the Publication Committee on one or two questions regarding the propriety of publishing certain items of news, and frequently the questions have also been referred to the Executive Committee. Since the Journal appears fortnightly, prompt action is often necessary in order that the publication can appear in time to be of immediate service to its readers.

Owing to the splendid cooperation between the officers and committeemen, the Executive Committee, the Committee on Publication, and the editors, the Journal now reflects the opinions, policies, and activities of the medical profession of New York State more fully and intimately than ever before. The Journal has adopted the standard of eighty pages for each issue distributed among the several departments according to the material on hand. A comparison of the pages in the several departments during the past three years is shown in the following table:

	1928	1929	1930
Scientific	585	639	537
Editorial	77	73	74
Medical Progress	96	96	96
Legal	83	68	62
News	238	207	220
Our Neighbors	139	127	137
Daily Press	48	48	48
Book Reviews	50	48	46
Advertising	636	653	615

The Journal is increasingly popular among advertisers, who are keen judges of the value placed on a periodical by its readers. The medical standards of our advertising have been kept up to those of our scientific pages, and failure to observe the standards have nearly always been due to the ignorance of laymen who handle the advertising. The editors have found the advertisers to be agreeable to any change which may be suggested.

COMMITTEE ON INSURANCE

The Commitfee on Insurance has reported regularly to the Executive Committee on its various activities. The most important report that it has made has been that the group insurance rate has been revised with considerable saving to the insured members. The basic rate on the fifteen five plan remains the same but on the larger policies has been reduced 16 or 17 per cent. The *x*-ray and radium policies have also been reduced.

The Committee presents to the House of Delegates for adoption the following resolutions which were approved by the Executive Committee under date of November 20, 1930:

Resolved, that the Medical Society of the State of New York, furnish to its members the services of an attorney at law in actions brought for alleged malpractice, under certain conditions to be hereinafter provided.

Resolved, that the Counsel of the State Society will act as attorney in all actions for alleged mal-

practice, brought against uninsured members in good standing of the Medical Society of the State of New York, who may be certified to by the Secretary of the Medical Society of the State of New York, as being entitled to the same.

Resolved, that any member in good standing of the Medical Society of the State of New York, shall not be entitled to defense for alleged malpractice claims while such member is residing and /or practicing medicine or surgery outside of the territorial limits of the State of New York.

Resolved, First. Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to membership in the State Society.

Second. Members who have been dropped for nonpayment of dues, if reinstated shall not be entitled to malpractice defense for acts committed during the time they were not members of the Society.

Third. Active members of the Society desiring to avail themselves of the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing in the State Society. They shall also furnish the Secretary, the Executive Committee and the Legal Counsel a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based, giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question, and shall furnish such other relevant information and execute such papers as may be required of them by the Secretary, the Executive Committee or the attorney of the State Society.

Fourth. A member shall agree not to compromise any claim against him, nor to make settlement in any manner without the advice or consent of the Society given through its attorney.

Fifth. In the event that a member sued or threatened with suit shall, without the advice or consent of the attorney of the Society, determine to settle or compromise any claim against him, he shall reimburse the Society for the expenses incurred in undertaking his defense, and in default thereof, he shall be deprived of further privileges under this resolution.

Sixth. The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims, or awarded by court verdicts, or for making payments for any purpose whatsoever.

Resolved, that the Society will not undertake the defense of any member who, after investigation by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide, or any criminal act or who has not complied with the recognized ethical laws in regard to these cases. The Society will defend only suits brought for any alleged malpractice, error or mistake done or claimed to have been done in the legitimate performance of the duties of his profession as a physician.

Resolved, that the Executive Committee of the Council shall have the power to decide whether or not a member is entitled to legal defense by the State Society against alleged malpractice claim or suit; and how many times, and to what extent he shall be defended for any claim or suit; and what aid shall be rendered in case of appeal from judgment of the court; and the procedure for conducting the defense shall be that embodied in the foregoing resolutions, and such other rules and regulations as the Executive Committee of the Council may authorize.

Resolved, that the Group form of malpractice defense with indemnity insurance adopted in 1921 for members of this Society be endorsed and commended, and every member be urged to avail himself or herself of this Group Insurance protection.

Resolved, that all resolutions herein adopted shall be deemed applicable to the Group Insurance Plan now in operation by the Medical Society of the State of New York, provided, however, that such resolutions as are pertinent be acceptable to the Insurance carrier.

Resolved, that a member in good standing of the Medical Society of the State of New York is entitled to malpractice defense by the Counsel of the Society, pursuant to resolution pertinent thereto, except, if at the time of the alleged malpractice claim, the member is carrying malpractice insurance and defense in any Insurance Company other than the Insurance Company under the Group Plan of the Medical Society of the State of New York, in which case the member is deemed to have waived any rights for malpractice defense by the Counsel of the Medical Society of the State of New York.

Resolved, that all previous resolutions heretofore adopted, pertinent to malpractice claims and defense, are hereby rescinded.

COMMITTEE TO REVISE THE PRINCIPLES OF PROFESSIONAL CONDUCT

The Committee to revise the Principles of Professional Conduct of the Medical Society of the State of New York presents the following amendments and additions to the Principles of Professional Conduct to the House of Delegates for ratification:

1. Page 1 remains as printed except that if the suggestions of the Committee are approved, the date mentioned in the 4th line should read "June 1, 1931" instead of "May 21, 1923."

2. The preface remains unchanged except

that at the bottom of the page the names of the present Committee should be substituted in place of the Committee as now printed.

3. Sections 1 to 30, inclusive of the Principles of Professional Conduct remain unchanged.

4. Sections 31, 32 and 33 are amended. A copy of the proposed amendments are appended.

5. Section 34 remains unchanged.

6. The Principles of Professional Conduct as now printed omit Section 35. Hence the present Section 36 becomes Section 35 and remains unchanged, and the present Section 37 becomes Section 36 and remains unchanged.

7. The present Section 38 becomes Section 37 and is amended in the manner appended.

8. The proposed Sections 38 and 39 are new. The Sections are appended.

9. Appendix I, which is the oath remains unchanged.

10. Appendix II, which is the recital of the medico-legal principles, remains unchanged except that in Section 8, page 13, the first word on the 6th line is changed from "doctor" to "physician."

Section 31 (a). Physicians shall not make use of, or knowingly aid or permit others to make use of them as subjects of, any form or manner of advertising or publicity through lay channels, either alone or in connection with others, which shall be of such character as to invite attention to themselves or to their professional position, skill, qualifications, achievements, attainments, specialties, appointments, associations, affiliations or honors and/or of such character as would ordinarily result in their self aggrandizement; nor shall they give to any person whomsoever whether for compensation or otherwise, any approval, recommendation, endorsement, certificate, report or statement with respect to any drug, medicine, nostrum, remedy, surgical or therapeutic article, apparatus or appliance or any commercial product or article, or with respect to any property, quality or use thereof, or any test, demonstration, or trial thereof, for use in connection with their name, signature or photograph in any form or manner of advertising through lay channels; nor shall they boast of cases, operations, cures or remedies or knowingly permit the publication of reports thereof through lay channels.

(b). Physicians should not become or remain associated or identified with any corporation, organization, group or individual, medical or lay, resorting to or making use of direct advertising to the public for business of a medical or therapeutic nature or having to do with the diagnosis, care or treatment of the sick or injured, the maintenance of health or the prevention of disease.

Section 32. Physicians shall not give nor offer, nor shall they undertake or promise to give, either directly or indirectly, any gift, gratuity, commission or bonus in consideration of or in return for the referring, recommending or procuring of any patient for medical, surgical or other treatment or in consideration of or in return for the referring, recommending or procuring of any person, specimen or material for diagnostic or other study or work, nor shall any physician request, solicit, accept or receive any such gift, gratuity, commission or bonus.

Section 33. Physicians should not hold any personal ownership in patents for any drug, apparatus, instrument or appliance used in medicine or surgery. Physicians should not request, solicit, accept or receive rebates or commissions from the prescribing of any agent used therapeutically. Physicians should not dispense or promote the use of secret remedies nor assist any person to evade legal restrictions governing the practice of medicine.

Section 37. Component county medical societies should cooperate with the properly constituted authorities in the enforcement of the laws of the State of New York and of their respective localities relating to the public health and to the practice of medicine and should report promptly to such authorities any evidence received by them indicating any violation of such laws. The commission of any act or acts by a physician which would subject him to reprimand or discipline or which would subject his license to practice medicine to revocation, suspension or annulment under the laws of the State of New York at the time, shall constitute a violation of these Principles of Professional Conduct.

Section 38. Any component county medical society, from time to time, may constitute, adopt, amend, alter and/or repeal, such further and additional regulations respecting professional conduct, binding only upon its own members, not inconsistent or in conflict with these Principles of Professional Conduct or with the intent and purposes hereof or with the Constitution and By-laws of The Medical Society of the State of New York, as such county society shall deem advisable for the reasonable regulation of the conduct of its members and the furthering of its aims and purposes; through by-law provisions adopted in accordance with the provisions of its own constitution and by-laws and of the Constitution and By-laws of The Medical Society of the State of New York.

Section 39. Each component county medical society is charged with the duty of carrying

out and enforcing, within their respective jurisdictions, the terms and provisions of these Principles of Professional Conduct. Any breach or infraction of any one or more of the terms or provisions of these Principles of Professional Conduct, or of any one or more of the terms or provisions of any further or additional regulations respecting professional conduct adopted as herein provided by any component county medical society shall subject the offender to and shall be sufficient cause for discipline. Each component county medical society, through by-law provisions adopted in accordance with its own constitution and by-laws and in accordance with the Constitution and By-laws of The Medical Society of the State of New York, (a) shall fix and determine the degree or degrees of discipline and the nature and extent of the penalty or punishment which may be imposed and (b) shall adopt its own rules and regulations of methods and procedure respecting all disciplinary investigations, proceedings and action. Interpretations and rulings of each component county medical society with respect to these Principles of Professional Conduct or with respect to any further and additional regulations respecting professional conduct adopted by it as herein provided shall be binding upon its members until modified, revised or reversed upon appeal by The Medical Society of the State of New York, or by a court of competent jurisdiction.

Respectfully submitted,
DANIEL S. DOUGHERTY, *Secretary.*

REPORT OF THE TRUSTEES

To the House of Delegates—
Gentlemen:

I have the honor to report for the Board of Trustees that the financial condition of our Society is very satisfactory.

The Board of Trustees was organized primarily to relieve certain officers of part of their irksome responsibilities and to devise a policy for the stabilization of the finances of the Society.

As a result of conferences between the Board of Trustees and the Secretary and Treasurer of the Society, the policy was established of investing our funds in carefully selected revenue bearing securities, the list of which is as follows:

$10,000 Fourth U. S. Liberty Loan 4¼% 1933-38.
8,000 American Telephone & Telegraph Co. 35 yr. S/F G/D 5% 1960.
3,000 Arkansas Power & Light 1st & Ref. Mtge. Series 5% 1956.
3,000 Canadian National Rys. Equip. Tr. Series K 1929 5% 1931.
4,000 Chicago, Milwaukee & St. Paul Ry. Co. Gen. Mtge. G/B Ser. "A" 4% 1989.
5,000 Cleveland, Cincinnati, Chicago & St. Louis Ry. Co. Ref. & Imp. Series "D" Mtge. Bd. 5% 1963.
3,000 Consolidated Gas Co. G/D 5½% 1945.
5,000 Erie Railroad Co. Conv. 50 yrs. Series "A" G/B 5% 1953.
3,000 International Great Northern RR. Series "B" 1st Mtge. 30 yr. 5% 1956.
5,000 New Orleans Texas & Mexico Ry. 1st Mtge. G/B Series "B" 5% 1954.
5,000 New York, New Haven & Hartford RR. Co. 1st Ref. Mtge. G/B 4½% 1967.
5,000 New York Power and Light Corp. 1st Mtge. 4½% 1967.
3,000 New York Steam Corporation "A" 1st Mtge. 6% 1947.
3,000 Norfolk-Western Ry. Co. 1st Cons. Mtge. 4% 1996.
3,000 Northern Pacific Ry. Co. Prior Lien Ry. & Land Grant 4% 1997.
8,000 Northern Pacific Ry. Co. Ref & Imp. Series C & D 5% 2047.
3,000 Pennsylvania Railroad Co. Const. Mtge. 4½% 1960.
3,000 Puget Sound Power and Light Co. 1st & Ref Mtge. Series "A" 5½% 1949.
5,000 St. Louis, San Francisco Ry. Consol. Mtge. Series "A" 4½% 1978.
8,000 Standard Oil of New Jersey Tem. Deb. 20 yr. Gold 5% 1946.
5,000 So. California Edison Company Ref. Mtge. 5% 1952.
3,000 Utah Power & Light Co. 1st 5% 1944.
3,000 Utilities Power & Light Co. G/B w/w 5% 1959.
5,000 Wabash Railway Co. Ref. & Gen. Mtge. Series "C" 4½% 1978.
5,000 Western Union Tel. Company 25 yr. Gold 5% 1951.

These securities were purchased after conference with recognized financial authorities.

At the present time the total amount of funds invested for the Society is $116,000, which in the year 1930 produced an income of $4,662.50.

These holdings are occasionally analyzed by three separate, independent financial experts,—one bank, one financial service and one brokerage house.

The analyses made by these three agencies correspond in major details and indicate that in our entire list of holdings there is none they would recommend for sale.

The Board of Trustees has also created three separate and distinct Trust Funds: viz.

First, the Journal Fund,
Second, the Directory Fund, and
Third, the General Investment Fund.

The income from the first two funds will ultimately cover the deficit incidental to these activities.

The General Investment Fund will ultimately produce an income which might be used for extraordinary disbursements or might be considered in the nature of a "War Chest" when and where needed.

The following Budget was prepared by the Executive Committee and approved by the Trustees:

Rent	$ 2,900.00
Telephone	200 00
Postage	600.00
Stationery and Printing	900.00
Salaries	18,000.00
Contingent Fund	1,000.00
Annual Meeting—Printing and Postage and Stenographer for House of Delegates	1,700.00
Printing District Branch Programs, and Postage for mailing paid through Secretary's Office	800 00
Auditor	600.00
Traveling Expenses—General Including President and Secretary	5,000 00
Traveling Expenses, A. M. A. Delegates	2,500 00
Counsel—Salary	14,000 00
Counsel—Expenses	257.41
Secretary—Honorarium	3,000.00
Secretary—Expenses	600.00
Executive Officer's Salary	9,000.00
Executive Officer's Expenses	1,500 00

Printing Directory	14,000.00
Wrapping and Delivery	1,700.00
Postage	700.00
Commissions	1,200.00
Stationery, Printing and Expenses	800.00

Although it is very gratifying to make a report containing so many conforting thoughts, it is only fair to say that the facts herein presented have been made possible very largely by reason of the active cooperation of our Secretary and the constructive suggestions of our invaluable Treasurer.

Respectfully submitted,

HARRY R. TRICK, *Chairman.*

April 15th, 1931.

REPORT OF THE BOARD OF CENSORS

To the House of Delegates:

Gentlemen:

There has been held during the year but one session of the Board of Censors.

The Board convened in the offices of the Society, 2 East 103rd St., New York City, on Monday, June 17, 1930, at 10 A.M., to hear the appeal of Dr. Edward S. Cowles against the action of the Medical Society of the County of New York excluding him from membership.

The following Censors were present: Drs. George B. Stanwix, Edgar A. VanderVeer, E. Carlton Foster, William L. Munson, Augustus B. Santry, W. Ross Thomson; William H. Ross, presiding; D. S. Dougherty, Secretary.

The appellant was represented by Mr. Samuel Untermeyer and Mr. George Gordon Battle; the respondent by Mr. Lloyd P. Stryker and Mr. Reed B. Dawson; Mr. Lorenz J. Brosnan acting as legal advisor for the Board.

At the end of three and one-half hours, the hearing adjourned, sine die.

Later by mutual agreement the appeal was withdrawn.

Respectfully submitted,

D. S. DOUGHERTY, *Secretary.*

April 15, 1931.

REPORT OF THE COUNSEL

To the House of Delegates—

Gentlemen:

Your Counsel herewith submits his report of the activities of the legal department of the Medical Society of the State of New York for the period from March 1, 1930 to and including February 28, 1931. Since your present Counsel did not take office until the first of April, 1930 this report covers, in addition to his own activities, a period of one month during which time his predecessor, Lloyd Paul Stryker was serving as Counsel to your Society.

Lloyd Paul Stryker resigned as Counsel for the Medical Society of the State of New York on the 31st day of March, 1930, and your Counsel was then appointed in his place and stead. Mr. Stryker had served as General Counsel for the Medical Society of the State of New York for a period of over four years. During his tenure of office he won the respect, admiration and affection of all with whom he came in contact. We believe that your worthy Secretary, Dr. Daniel S. Dougherty expressed the sentiments of every member of the Medical Society of the State of New York when, in commenting on Mr. Stryker's resignation, he said: "Through the resignation of Mr. Lloyd P. Stryker as our Counsel the Society has experienced a great loss and to the Secretary the loss has been both official and personal. During the years Mr. Stryker has been with us the Society has grown to appreciate not only his work but also his personality. He was the friend of every member of the Society, looking upon the physician as a man necessarily of high ideals and character and always judging him as such. He proved himself a man and 'to know him was to love him.'"

Your present Counsel has been identified with the work of your Society since 1920 and hence was fully familiar with every phase of the activities of the office of the General Counsel, and during the tenure of office of his predecessors, George W. Whiteside and Lloyd Paul Stryker, he had conducted the defense of a great number of malpractice actions.

During the recording period we suffered a severe loss in the sudden death of Mr. Maxwell C. Klatt, the Attorney for your Society. Mr. Klatt had been identified with medico-legal work for nearly a decade, having served under Mr. Whiteside, Mr. Stryker and your present Counsel. Upon Mr. Klatt's death, the Executive Committee appointed the writer's associate Mr. Thomas H. Clearwater to the position of Attorney previously held by Mr. Klatt. Mr. Clearwater, a graduate of Yale University and Columbia University Law School and a nephew of former Supreme Court Justice Alphonzo T. Clearwater, brings to his official position a wide legal experience and in addition those personal qualities of integrity and honor so essential to the successful representation of your Society and its individual members.

Your Counsel wishes to acknowledge his appreciation of the spirit of cooperation shown by the officers of your Society. He has come to know many of them very well and to cherish highly their friendship. It has been a real pleasure to serve under your President, Dr. William H. Ross who, since taking office, has travelled throughout the State in the interests of your Society. Your efficient and worthy Secretary, Dr. Daniel S. Dougherty is a tower of strength to your profession; he brings to the office of Secretary a wide and varied experience in medical problems, a keen and perceptive judgment as well as marked gifts of leadership. Your Counsel wishes also to acknowledge his indebtedness to your Speaker, Dr. John A. Card and to your Treasurer, Dr. Charles Gordon Heyd (who together comprise the Insurance Committee) for their splendid cooperation and excellent judgment in the problems which have come before them for decision. Your Counsel has greatly enjoyed his relations with the members of your various committees with whom at one time or another he has been in conference and consultation.

At this point the writer also wishes to record the fine work of his loyal and devoted office associates whose wholehearted endeavors have contributed in no small measure to the results shown by this report.

We are pleased to be able to report that in the latter part of this year there will be ready for publication a book defining the legal duty of a physician in relation to his patient. This work will set forth the principles of law that apply between patient and physician, with the adjudicated cases of the courts setting forth such principles. The author is your former Counsel, Lloyd Paul Stryker. This book will constitute a practical legal guide to the individual practitioner. The writer has been in frequent conference with Mr. Stryker about this work, has offered numerous suggestions with respect to the make-up of the book and has read the manuscript thus far prepared. We believe that when published this volume will fill a real need in the professional life of the individual doctor.

In making his report, your Counsel adheres to the convenient category employed in previous years whereby his activities have been divided into three main divisions: (a) the actual handling of malpractice actions before courts and juries and in the appellate tribunals; (b) counsel work with officers, committees and individual members

of the Society, and (c) legislative advice and activities

Litigation

The practice of medicine and surgery is an extra-hazardous profession This should be recognized at the outset It must be remembered that the physician's rights in our courts are passed upon by twelve men unversed in medicine or surgery So much has been said on this subject both by your present Counsel and by his predecessor, through the written and the spoken word, that it would be a work of supererogation to enlarge upon this point To be sure cases without merit are instituted against physicians — many that could properly be termed strike suits On the other hand, as has been so often said in these annual reports of Counsel there are cases where the physician sued unfortunately has failed in some particular to follow the approved methods in general use among competent physicians Cases of this kind have been settled However actions in which the writer has felt that the physician has a valid defense have been vigorously fought We do not attach any nuisance value to our cases thus serving notice on the attorneys who bring malpractice cases that they cannot obtain any settlement merely by the commencement of an action But for the principle here enunciated, which has been steadfastly adhered to since the inception of our group plan in 1920, our physicians would be swamped with claims and suits for malpractice

From Table I it will be noted that in the past year only 26 cases have been settled as compared with 28 in the preceding year On the other hand 286 actions were instituted in the period here reported on as compared with 192 in the previous period This difference is accounted for in large measure by the fact that at the close of the last accounting period there were pending between 150 and 200 claims In Counsel's last report it was said with respect to these claims that "actions have not yet been begun, but many of which ultimately will result in actions in court" Many of these claims did result in actions during the period covered by the

present report. In many others we were successful in persuading the claimant not to commence an action against the physician.

It will be noted that in the present period 159 cases were disposed of as compared with 144 last year, representing an increase of 15 disposals. Of the number of cases disposed of only 26 were settled; in 130 either judgments for the defendant have been secured or they have been disposed of through dismissal, discontinuance or abatement. Throughout the reporting period only 3 cases resulted in judgments for the plaintiff, and of these 3 one is now on appeal. On February 28th of this year there were actually pending in court 578 cases as opposed to 451 of the preceding year. These figures do not, however, include a large number of claims now pending in which no action has yet been started, but undoubtedly many of them will result in actions in court. The figures in the accompanying Table I are self-explanatory and we feel require no further comment.

Also the ever-increasing value of our group plan renders it unnecessary to go into this subject at any great length. Time and again physicians who have been sued and who have not taken advantage of the benefit of our group plan have expressed themselves as deeply regretting their failure to obtain insurance. A lawsuit is not a pleasant experience, but at least the physician who has obtained adequate insurance is free from the worry and mental strain which comes to a physician who is facing a malpractice action without financial indemnity. It should be noted at this point that a physician who permits his insurance to lapse finds himself in exactly the same position, so far as financial benefit is concerned, as the non-insured doctor if a claim is brought against him arising subsequent to the time when his policy became inoperative by reason of such lapse.

It is pleasing to record that the carrier under our group plan has cooperated to the fullest extent with your Counsel and has at all times, in relation to your Society as well as its individual members, displayed a spirit of fairness that has won the commendation of your Insurance Committee. The recognition by individual members of your Society of the fruits and benefits of the group plan is due in large measure to the indefatigable labors of your efficient Insurance Committee. The Committee is made up of Drs. John A. Card and Charles Gordon Heyd. Each year Dr. Card goes throughout the State speaking to the members of the various component county societies on the benefits of malpractice insurance. The results of his labors in this respect are matters of record. Excellent work has also been done in this field by the Society's authorized indemnity representative, Mr. Harry F. Wanvig.

We append hereto Table II which gives a comparison of the number of members insured in 1928, 1929, 1930 and 1931 and the number of members in the county societies and the percentage of insured members in the county societies and in the entire State Society. These figures are sufficiently clear to obviate the necessity of extended comment. It will be noted that there are now 12,812 members of the State Society as compared with 12,314 in the previous reporting period, and that there are now 7,334 insured members as compared with 7,170 in the previous period.

Counsel Work

During the period of this report, your Counsel has prepared for publication in the Society's Journal articles in the nature of editorial comment. These editorials have included the following:

"Bootleg Insurance" Attacked by the New York Superintendent of Insurance.
Defendant's Right to X-ray Examination of Plaintiff in Personal Injury Actions.
Attorneys, Courts' Inherent Power of Discipline.
Habit Forming Drugs—State Statutes Analyzed.
The Institute of Law of Johns Hopkins University.
Liability Insurance—Necessity of Assured Giving Prompt Notice.
A Doctor's Certificate.
The Defendant's Right to Blood Test of Plaintiff in Personal Injury Actions.
Insurance Policy—Distinction between Accident and Disease.
The Doctor as an Executor.
Medicine and Law Join to Save the Life of a Child.
Confidential Communication—Waiver of Privilege by Patient.
Expert Testimony and the Use of Medical Textbooks.
A Salutary Decision.
Malpractice—Statute of Limitations.
Executor and Trustee—Amount of Commissions.
Husband and Wife—Court's Refusal to Annul Marriage on Ground of Epilepsy.
Confidential Communications between Physician and Patient.
A Just Censure.
Criminal Law—Confession Secured by Threats and Violence Condemned.
Our Group Plan—A Physician's Claim for Reimbursement Examined and Disallowed.

Your Counsel has also digested and there have been published in the Journal reports upon malpractice action which it has been felt were of special interest to the profession. The case reports published during the previous year are as follows:

Claimed Negligence in Setting of Compound Fracture of Finger.
Claimed Negligence in Treating Scars with Nitric Acid.
Facial Paralysis Resulting from Claimed Negligence in a Mastoid Operation.
Claimed Negligence in Caesarian Section, Resulting in Death.
Claimed Injuries Received during Claimed Negligence in Confinement.
Death Claimed Due to Mustard Bath.
Claimed Wrong Diagnosis of Ectopic Pregnancy

Claimed Negligence in Causing Burn during Hernia Operation.
Inflammatory Reaction from the Use of Picric Acid.
Claimed Negligence in Removal of Broken Needle.
Claimed Negligence in Failure to Discover Carbuncle on Neck.
Blindness Claimed Due to Negligence in Treating and Operating Upon Lacerations of the Eye.
Retention of Sutures Claimed Due to Neglect.
Claimed Failure to Repair Laceration Sustained during Delivery.
Claimed Negligence in Setting of Fractured Radius and Ulna.
Claimed Negligence in Reducing a Fracture of the Arm.
Death Occasioned by an Administration of Anaesthesia.
Alleged Negligence in Skin Grafting Operations.
Claimed Negligent Breaking of Needle during Novocaine Injection.
Alleged Unauthorized Removal of Appendix.
Claimed Negligent Treatment of Powder Wound.
Claimed Negligence Causing Needle Break.
Claimed Negligence in Diathermic Treatment of Leg.
Claimed Negligent Operation on Eyelid.
Alleged Negligence in Tonsil Operation.
Claimed Negligent Treatment of Scrotal Hydrocele.
Alleged Negligence in Treating Injured Finger.
Death Claimed Due to Failure to Detect Heart Condition during Pregnancy.
Alleged Negligent Treatment of Hemorrhoids.
Death Claimed Due to Negligence in Caesarian Section.
Death of Child Alleged to Have Been Caused by Doctor's Negligence.
Alleged Negligent Treatment of Mastoid Wound.
Claimed Negligence in Removal of Cartilage from Nose.
Claimed Negligent Treatment of Neuralgia.
Alleged Negligent Tuberculin Injections.
Alleged Negligence in Prescribing Mercury Injections.
Alleged Negligence in Failure to Complete Operation.
Pan-Sinusitis and Otitis Media.
Tonsillectomy, Removal of Uvula.

It is pleasing to your Counsel to find that these editorials and case reports are read by the members of your Society with great interest and approval.

In addition to his other duties, your Counsel receives frequent requests for opinions on various subjects. It should be remembered that the Executive Committee of your Society has ruled that all requests coming from individual members of your Society or from component county societies must, in the first instance, be referred to that body for action. If the Executive Committee deems the inquiry a proper one for opinion by legal Counsel, it refers the same back to him for reply. Some of the matters upon which advice has been thus rendered are as follows:

Inquiry regarding the legal liability of physicians who experiment in treatment of patients.

Inquiry as to whether the group policy of insurance covers a physician as manager of a public hospital.

Inquiry as to whether the State Society will defend a physician in a civil action growing out of an abortion.

Inquiry regarding the legal responsibility of a physician who elects to do his own interpretation of X-ray plates, and as to whether additional insurance protection would be advisable in such cases.

Inquiry regarding the reliableness of a foreign insurance company not authorized to do business in this State.

Communications regarding the legality of giving information to insurance companies for statistical purposes.

Inquiry regarding the legality of taking a Wassermann test of all patients entering a hospital.

Inquiry as to whether the statutes directing physicians to report all cases of syphilis to the local Boards of Health are mandatory or discretionary.

Inquiry as to whether, where a physician has expressed a willingness to continue to treat without charge, his duty is to call at the patient's home where the child is in fit condition to be brought to the doctor's office.

Examination of the statutes in regard to the following inquiries:

(a) Is a registered nurse permitted to administer anesthesia for surgical or obstetrical operations?

(b) Does the administration of anesthesia come under the Medical Practice Act?

(c) In case of accident due to faulty administration of anesthesia at the time of operation, is the hospital or the attending surgeon liable to malpractice suit?

Inquiry as to the advantage of a group plan policy as opposed to a malpractice insurance policy with a foreign insurance company not authorized to do business in this State.

Inquiry as to whether the submission and payment of a doctor's bill for services affects the patient's right to recover, and as to the advisability of submitting such bill before the Statute of Limitations in malpractice actions has run.

Your Counsel has also rendered opinions in respect to the following inquiries which were referred by the Executive Committee to the Committee on Group Insurance in conjunction with Counsel:

Inquiry as to whether a physician is compelled by his group insurance policy to assign a judgment for costs in a malpractice suit to the group carrier where the plaintiff is impecunious.

Inquiry as to coverage under the group plan in so-called "property damage" (loss of service) suits.

Inquiry regarding the status of a State Society member who becomes a non-resident, in regard to membership in the Society, protection against malpractice suits and the effect of such removal upon his group plan policy of insurance.

Opinion of Counsel has been requested by the Executive Committee and has been rendered as to the following matters requiring examination of the statutes and judicial decisions:

The legal status of a State Society member who has been suspended from the rights and privileges of the Society.

What constitutes the practice of medicine by corporations, and how is the term "practicing medicine" defined by judicial decisions?

The rights of the NEW YORK STATE JOURNAL OF MEDICINE under its present contracts to cancel unethical advertisements.

Proposed revision of the contracts between the NEW YORK STATE JOURNAL OF MEDICINE and advertisers.

In addition to the matters referred to under this heading, your Counsel also acted as counsel to the Board of Censors of your Society in two appeals brought before that Board for decision.

Legislative Advice and Activities

Throughout the reporting period various bills of interest to the medical profession have been introduced in the Legislature We have been requested to render an opinion with respect to many of these, and our advice and opinion have been promptly given The usual chiropractic bill was introduced, and this bill we made the subject of comment in our editorial of March 1st of this year

Conclusion

The writer deems it a great privilege and a pleasure to have represented your Society and its individual members The position of General Counsel of the Medical Society of the State of New York is a position of great trust and honor Its obligations are many and varied Yours is a noble profession, your work is sometimes misunderstood by the lay public and frequently unjustly criticized Your Counsel has endeavored in his contacts with courts, juries and lawyers to bring about a better understanding and a keener appreciation of the splendid and unselfish work that is being done by the medical profession

Respectfully submitted
LORENZ J BROSNAN, *Counsel*

March 1, 1931

REPORT OF THE COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

To the House of Delegates—

Gentlemen

In the preparation of the annual report of the Committee on Public Health and Medical Education to the House of Delegates the reports of this Committee for the previous five years have been carefully reviewed This review indicates that there has been a definite trend in the work of the Committee Its policy may be summed up briefly as consisting of two parts *One* the investigation of public health activities and the education of the physician in such matters *Two* the contribution in the field of public health on the part of the medical profession in aiding to provide adequate medical care through the continued instruction of the physician by means of graduate education

Graduate Education

As in the past, the largest part of the Committee's attention and funds have been devoted to graduate education The following is a report of the courses sponsored by the State Society under the direction of this Committee during the current year (The figures after each course indicate the number of lectures in that course)

Fall of 1930

Rockland Seneca Wayne Monroe Livingston)	Heart Disease	5
Genesee (with Orleans & Wyoming)	Tuberculosis	5
Tioga	Periodic Health Examination	4
Cortland	General Medicine	6
Washington	Clinical Day	5
Sullivan	Traumatic Surgery	6

Spring of 1931

Dutchess Putnam	Internal Medicine	5
Schoharie	Surgery	6
Otsego	Surgery	6
Onondaga	Surgery	6
Cayuga	Surgery	6
Steuben	Traumatic Surgery	6
Chemung	Traumatic Surgery	6
Tompkins	Heart Disease	5
St Lawrence	Traumatic Surgery	6
Jefferson	Traumatic Surgery	6
Clinton	Internal Medicine	6
Franklin	Internal Medicine	6

Following its custom of the past years the Committee has kept detailed records of the courses which it has sponsored In as much as the work of the current year is not completed at the time of the writing of this report a summary can only be given of the courses held before January 1, 1931 This is as follows

Total number of courses	9
Total number of lectures	41
Number of county medical societies before which courses were given	13
Total attendance of all courses	1 237
Largest attendance for one course (Monroe)	566
Smallest attendance for one course (Tioga)	59
Total cost of all courses	$1 862 02
Average cost per course	206 89
Average cost per county	143 23
Average cost per attendance	1 51

However, the entire work for the previous year 1929 30 can now be given The figures for the two previous years are also tabulated for the sake of comparison as well as such information as can be reported for the current year at this time

	1927-28	1928-29	1929-30	1930-31
Total number of courses	21½	21½	16	21
Total number of lectures	116	105	91	116
Number of county medical societies before which courses were given	22	31	19	25
Total attendance of all courses	3,268	4,809	3,296	
Largest attendance for one course	(Albany) 495	(Monroe) 836	(Monroe) 841	
Smallest attendance for one course	(Greene) 42	(Herk.) 66	(Rock.) 57	X
Total cost of all courses	$ 4,524.82	$ 4,777.07	$ $3,705.42	
Average cost per course	215.47	217.96	231.59	
Average cost per county	205.67	154.10	195.02	
Average cost per attendance	1.38	.98	1.12	

These figures indicate that the work has continued much the same during the past four years. There has been a slight variation in the total number of courses and the number of counties before which courses have been given. However, in each year approximately one-third of the component county societies have been reached in this work. The attendance during the year 1928-29 was much higher than in other years. This apparently was due to the fact that during that time the lectures were on subjects of the most practical interest. The figures indicate that the cost of the work has gradually been reduced. It is expected that there will be no increase shown in the figures for the current year.

An analysis of the Committee's experience of graduate education indicates definite lines along which this work should be carried on. The lectures must deal with practical subjects. In order to meet the needs and the demands of audiences whose interests are so diversified they can not be too highly technical nor can prolonged instruction be given on any one subject. The lectures must continue to be distinct from the regular meetings of the county society, though occasionally an exception may be made for the lecture to replace the scientific program of the county society. The experience of the Committee indicates that it is well for small adjacent counties to join a large metropolitan county in this work especially where travel facilities are most convenient. Also better results follow the plan, rapidly being adopted, of two nearby counties having identical courses both of which can be given on the same day. The reasons for the above statements are too obvious to need comment.

Some of the courses sponsored by the Committee have not been as satisfactory as others. Criticism of the courses may be justified on the grounds that the subjects have not been of enough practical importance to attract the attention of the physician or that the lecturer has failed to present the subject in a practical way or that the lecturer has lacked the ability to make his talk interesting as well as instructive. The Committee is constantly trying to correct these faults wherever they occur. It is making preparations for courses to be available during the next year which will deal with most practical subjects such as Acute and Chronic Infections, Pre-clinical Signs of Disease, Emergencies, Functional Diseases and Treatment. These courses will be made up by the Committee itself after consultation with various medical teachers outside the Committee. The scope of each lecture will be definitely outlined so that the services of difference lecturers can be utilized for one subject. The Committee will be very careful in selecting these lecturers and hopes to be able to secure men of wide clinical experience thoroughly accustomed to speaking to present these subjects. Where courses have not been completely satisfactory to county societies, in some cases, criticism of the society itself in this regard is justified. In the first place some societies have made unwise selection of courses, usually despite advice of the Committee. This mistake can be obviated by having a strong committee on graduate education in the county society appointed early in the year which would give sufficient time to discover the wishes of the society as well as to confer adequately with the State committee and to be guided to a proper extent by the latter body. Many of the county societies are doing this at the present time. Secondly, some county societies have selected an unsuitable time for the course to be presented due to conflict with other medical meetings either in various parts of the county or elsewhere. Thirdly, some counties still fail to give adequate publicity regarding the course to its members as well as to other physicians in the county. A strong committee on graduate education in the county society would eliminate all these mistakes.

That graduate education is rapidly becoming an integral part of other State medical societies is indicated by a pamphlet issued by the University of Virginia in connection with the Medical Society of Virginia. According to this pamphlet, "Various plans in thirteen American States, Colorado, Iowa, Michigan, Minnesota, Missouri, New York North Carolina, Ohio, Oklahoma, Oregon, Pennsylvania, West Virginia and Wisconsin, are known to have been inaugurated, with different degrees of success, as State programs of graduate medical education." Summarizing the data from these States the pamphlet states that New York has the largest undertaking conducted by a strong State society on the most

X—(Data not available until July 1, 1931)

generous plan. The entire work of the Medical Society of the State of New York in graduate education is reviewed in detail in this pamphlet and a number of the features of our activities are cited as being worthy of special comment.

During the past year the Committee tried out the plan of substituting a clinical day of several lectures in place of the usual method in which one lecture was given at weekly intervals. The results in this instance were not satisfactory and while a poor choice of time as well as a bad selection of the part of the county in which the lectures were held may have been largely responsible for this, nevertheless, it is the feeling of the Committee that the majority of physicians prefer the weekly single lecture. Conference with representatives of various county societies tends to justify this statement.

During the past four years there have been 80 courses comprising 428 lectures. Of these 21 have been on the subject of internal medicine as outlined by Dr. Walter W. Palmer of New York City and have reached 27 county societies. Seventeen were courses on Heart Disease outlined by Dr. John Wyckoff of New York City and these have reached 23 counties. Several counties have had a course each year. Two counties have had a course each year since the work was first started through cooperation with the State Department of Health. During the present year one county (Dutchess-Putnam) which previously had had no course is having its first course. Another county (Seneca) in which no course hitherto had been given but which had joined with nearby counties for previous courses has had its own course for the first time this year. No courses in graduate education have been given in Allegany, Madison, Richmond, Schuyler and Westchester Counties. The proximity of Westchester County to the city of New York with its tremendous facilities for graduate education may nullify the need for a course in that county. The comparable inaccessibility of Richmond County to the rest of the city of New York does not justify the same conclusion.

The Committee especially recommends to county societies for consideration for future study a course on Tuberculosis as also courses in Obstetrics and Pediatrics, neither of which subjects have been presented during the past three years. The beneficiary results of a graduate course to county societies as well as the benefits to the public in general, together with the interest of the physicians in the course justify the continuance of this work which it is now demonstrated can be carried on without undue expense.

Other Activities

The Committee has arranged and aided county medical societies in preparing the scientific programs and obtaining speakers for regular county society meetings. It also aided in the preparation of the scientific program of two district branch meetings. It has postponed temporarily publication in the State Journal of short articles dwelling on the importance of preventive medicine in the regular work of the physician, in as much as the Committee on Periodic Health Examinations had under contemplation the publication of somewhat similar material but in a more detailed way. The Committee at the present time is not in favor of a graduate course on Periodic Health Examinations feeling that better results would be obtained from one lecture on this subject.

The Committee is maintaining its interest in general public health activities and endeavoring to stimulate county societies to appoint active committees on this subject. The activities of the Public Health Committee of the County of Monroe are especially noteworthy. This Committee, under the chairmanship of Dr. E. G. Whipple, has dealt with Tuberculosis, Heart, Cancer, Social Hygiene, Child Welfare, Diphtheria Prevention, Mental Hygiene, Pre-natal Care, Health Education, and Periodic Health Examinations. Its messages over the radio have reached so many as to make a long review of its work unnecessary. The activities of this county should serve as a model for other county societies to follow. The need for such committees is especially urgent at the present time in view of new health legislation about to be enacted in this State. It is regrettable to have to admit that the Committee on Public Health of the State Society as well as county societies have not been consulted about these matters either during the period of their investigation or during the construction of legislative bills. The Monroe County plan of having sub-committees on the various phases of public health under the direction of a general committee on public health might well be considered by the State Society where the tendency to appoint special committees on subjects within the province of standing committees has been steadily growing.

During the year the Committee cooperated with the State Department of Health in making available to county societies information regarding the possibility of an increased incidence in measles in certain parts of the State and methods for the control of the same. It offered its services to the State Department of Health in arranging in specified sections of the State intensive courses in the treatment of this disease and its complications.

The Committee is still investigating the subject of maternal mortality and in this regard still urges legislation requiring the licensure of all private hospitals. The Committee was invited to partake in a study of maternal mortality by the Department of Health of Cattaraugus County. As this was an activity limited to one county the

Committee felt that it should be referred to the local county society and in the meanwhile that society has been informed that the Committee's services in an advisory capacity are available to it if requested.

The Committee on two occasions has sent information to the White House Conference regarding its work in giving instruction in Obstetrics and Pediatrics. For the President of the State Society it compiled a list of all courses given in all counties of the State since July 1, 1924.

The Chairman of the Committee has attended all the Executive Committee meetings of the State Society held during the year, three meetings of the Public Relations Committee and one each of the Committee on Physical Therapy and the Committee on Periodic Health Examinations. He has attended the President's Conference of the chairmen of standing committees, the conference of secretaries of county societies, the conference of chairmen of Public Relations Committees and with three other members of the Committee attended a conference of the State Department of Health. He has attended meetings of the Executive Committee of the Fifth and Eighth District Branches and the Third and Seventh Annual District Meetings. He has attended meetings of the following county societies; Genesee, Wyoming, Orleans, Chemung, Cayuga, Otsego, and held conference with representatives of the Societies of Steuben, St. Lawrence and Jefferson.

The Committee has continued to operate well within the limits of the appropriation made to it each year, and it has tried to be economical in the expenditure of its funds without, however, affecting its work to disadvantage. It has in its files accurate records of all its activities, readily accessible, as well as the business-like system of its accounts.

Again the Committee wishes to express its sense of obligation and appreciation to the many lecturers who have so generously given their time for graduate education and especially to Drs. John Wyckoff, Walter W. Palmer, Edward R. Baldwin, Alan R. Anderson, John J. Moorhead, and Charles Gordon Heyd, who have outlined courses and organized groups of instructors for the work. The Chairman of the Committee wishes to express his appreciation to the members of the Committee for their wholehearted cooperation and active interest. Acknowledgment is again made of the excellent cooperation extended by the other committees of the State Society, particularly of the most cordial relations that have continued to exist between the chairmen of these committees and the chairman of this committee. As in the past the Secretary, Treasurer, and the Executive Officer have been most kind in their aid to the Chairman and members of this Committee and it has been an inspiration as well as source of personal pleasure to serve as Chairman of one of the standing committees under the excellent leadership of President Ross.

Respectfully submitted,

THOMAS P. FARMER, M.D.,
Chairman.

April 15, 1931.

REPORT OF THE SPECIAL COMMITTEE ON CANCER PREVENTION

To the House of Delegates—

Gentlemen:

Your Special Committee on Cancer Prevention begs leave to submit the following report for the current year.

The Special Committee on Cancer Prevention held a meeting on Friday, October tenth in New York City and adopted the following recommendations:

(1) The Committee felt that each county medical society should devote at least one meeting a year to the subject of cancer.

(2) The Committee advised that a list be prepared of physicians who were capable and willing to give talks on cancer before county medical societies, especially emphasizing the responsibility of the doctor in the question of cancer.

(3) It is recommended that the Committee arrange to provide speakers as coming from the State Medical Society for public programs arranged for the American Society for the Control of Cancer or any of its branches when requested to do so.

(4) The Committee desires to cooperate with the American Society for the Control of Cancer or any of its branches.

(5) It was decided that a questionnaire be sent to the deans of all medical colleges of the state in order to survey what is being done in teaching cancer prevention to medical students. Dr. Burton T. Simpson agreed to prepare a letter and questionnaire dealing with this subject to be sent to the deans.

(6) It was left to the Committee on Public Health and Medical Education to arrange with county medical societies for a meeting each year to be given over to the discussion of cancer.

Through the office of the Committee on Public Health and Medical Education a letter was sent to the secretary of each county medical society

urging each county society to devote at least one meeting a year to the subject of cancer. Twenty-two replies were received and at the time of the writing of this report there have been meetings at which this subject was discussed in nine county societies. Five other county societies are planning such meetings in the very immediate future and six county societies have the matter under consideration. Several of these meetings were arranged with aid from the Committee on Public Health and Medical Education.

Complying with the second recommendation of the Committee a list has been prepared of capable speakers on the subject of cancer, who are willing to give talks before county medical societies.

The questionnaire prepared by Dr. Simpson was sent to the deans of all the medical colleges of the State and all but one replied. This information is in the hands of the members of the Committee for study at the present time.

The Committee's plans for the future are along the policies indicated in this report.

Respectfully submitted,

THOMAS P. FARMER, *Chairman.*

April 15, 1931.

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

To the House of Delegates—

Gentlemen:

Your Public Relations Committee has continued its work along the lines adopted during the previous years and is encouraged in its efforts by many very apparent evidences of cooperation in health work which are noted in our county medical societies, and in letters of inquiry received relating to the work of the State Committee and its County Units.

There seems to be an ever broadening field of activity, likewise a definite realization upon the part of the medical men of the necessity of their cooperating with all health agencies, whether lay or governmental, and of their pushing forward, to a greater extent than formerly, the newer ideas in medicine relating to health measures and the prevention of disease. It is worthy of note that very few controversial questions have come before your committee for adjustment.

The personnel of the committee remains as of the previous year, except that our Ex-President, Dr. George M. Fisher, who during his term as President of your State Society, conceived the idea and originated this committee, has honored it by accepting appointment to the position left vacant by the advancement of Dr. Ross to the Presidency.

The committee has met monthly, in New York or Albany, to discuss and consider the many problems to be dealt with relating to the work.

The members of this committee have been active in addressing County Societies, District Branch meetings and various medical gatherings with reference to the necessity of vigorously carrying on the work of the County Medical Society Public Relations Committees, thus endeavoring to activate county committees to as great an extent as possible.

Health surveys from nineteen counties in the State have been received and published in the New York State Journal of Medicine. We regret that more of the County Society Public Relations Committees do not comply with our request for such surveys. Much important cooperative health work is going on in our counties and it is not given proper publicity. A basic survey submitted to this committee and published in the Journal, followed by an annual report, would overcome the present condition, likewise give the State committee a definite knowledge of existing conditions.

Bulletins and letters relating to the work to be performed by the County Committees have been regularly submitted to them and to others interested in the activities of this State Committee. We aim to keep the county society committees informed of the activities of the State Committee and of what is expected of them as county committees, and have stressed the point that our County Society Public Relations Committees must be made up of leaders in the medical profession, that they must be aggressive and cooperative; for their success will depend upon the ability of the members to impress the public with the viewpoint of organized medicine and to secure active cooperation of other Public Health agencies.

A Conference of the Chairmen of the Public Relations Committees of the County Medical Societies of this State was held in Albany September 18, 1930. At this meeting 32 County Medical Societies were represented by the chairmen of their respective County Society Public Relations Committee or by some one designated to represent it. In addition there were present the President, President-Elect, Secretary and other officers and committeemen of the Medical Society of the State of New York.

The agenda for this conference centered, principally upon the pertinent subject—

"How can we develop an active Public Relations Committee in each County Medical Society?"

The following principles were recommended to the County Committees:

1. The activities of each county committee should consist in expanding the health work which is already being undertaken in the county, by any organization, as well as to initiate new measures.
2. The members of each county committee shall seek to establish intimate contacts with the leaders of every volunteer health organization in the county. They shall not wait for invitations to cooperate with the lay organizations, but shall take the initiative, if necessary, in proposing it.
3. The Committee shall offer the advice and assistance of the medical profession as to the most practical ways of conducting any form of health service in the county, and if possible, shall see that every health organization in the county shall include at least one local physician on its governing body.
4. The State Committee on Public Relations is in the position to give consultation and advice to any county committee in caring for its problems in the field of Public Relations.

The discussion participated in by twenty-two of the members present was intensive and inspiring, demonstrating that in many of the counties real progress is being made far in advance of what we could have anticipated for the limited period of time that these committees have existed. Furthermore, this conference demonstrated that the personnel of the county committees had been well selected, as the chairmen present were the leaders in their respective county societies, men who recognize that there is an issue at stake and will seek out its solution. To those of us who have been hoping to see definite leadership by our County Public Relations Committees, it was most encouraging and inspiring to note the personnel and intensity of mind of those present.

We, as a committee, are impressed that this was an important conference and fully justified the expenditure of money, and would recommend that it be continued each year.

Your Committee has given much time, thought and consideration to the Rules and Regulations to govern the developing County Hospitals that are to receive State aid. These hospitals are general hospitals and the one at Warsaw in Wyoming County is in active operation. The second one in Lewis County is in the course of construction.

The following Rules and Regulations were recommended by your committee and received the sanction of the Executive Committee:

1. All registered physicians residing in the county shall be eligible to membership on the staff. Physicians residing outside of the county may use the hospital, but cannot become voting members of the staff.
2. From their number they shall nominate for election by the board of managers a medical board of not less than five members.
3. The medical board, subject to the approval of the board of managers and the State Commissioner of Health, shall have supervision and control of all medical service in the hospital. This shall include appointments for the necessary, efficient and adequate surgical, medical, special and nursing services of the hospital; the preparation of rules and regulations for the conduct of the professional work of the hospital and the formulation of whatever by-laws seem necessary for the efficient conduct of its (medical board's) business.

As indicated by this resolution, the committee was unanimous in feeling that every provision should be made to guarantee the privileges of these county hospitals to every practicing physician in the county.

We are much impressed by the importance of seeing that the developing State-aided county hospitals shall be of real worth to the public and of definite advantage to the medical profession practicing in those counties. Your committee wishes to express its appreciation to our President Dr. Ross, for the intense thought, careful study and wise counsel that he has applied to this subject. To him is due much of the credit for having placed this project in its present satisfactory condition.

A study of the Health Services in Colleges and Universities of New York State by one of our committee, Dr. O. W. H. Mitchell of Syracuse, has been made and published in the New York State Journal of Medicine of November 1, 1930. This represents a piece of work which will be invaluable in its influence in leading to better education in health matters, thus instilling into the minds of the youth of our State a proper appreciation of health and disease prevention. Reprints of this study were obtained and distributed widely.

Throughout the past years that your committee has functioned it has been dealing with problems relating to Public Relations as existing in the so-called up-State section and has not attempted to delve into the many and intricate problems of the Metropolitan area. This came about largely from the fact that we were gradually feeling our way, educating ourselves as to the scope of our work and planning for the future. After four years of intensive work in the area above the Bronx we were pleased to entertain from various officers and members of the organized medical body of the five counties of the Metropolitan District invitations to cooperate with them in their desire to establish better medical public relations. Such a contact was made January 8, 1931, when our committee met in New York City with representatives of the five County Medical Societies and discussed methods for betterment of Public Relations and furthering the activities of a coordinating committee, which had been in existence for some time, by adding to it a sub-committee from the State Public Relations Committee. The following motion was adopted:

"It is recommended to the State Committee on Public Relations that it appoint a sub-committee which in operation may act in an advisory capacity with the Five County Coordinating Com-

mittee." Such sub-committee was appointed and is cooperating with the Five-County Committee by meeting with it monthly and studying the problems of the Metropolitan District. We are already convinced that the State Society should develop an increasing interest in the medical affairs of the great city which seems destined to become the foremost medical center of the world.

Your committee thought wise to appoint a sub-committee composed of Drs. Hambrook, Fisher and Lawrence to make a study of the following laws: 1. The law relating to the medical care of the physically handicapped child.

2. The Public Welfare Law.

Such committee has reported as follows:

In that portion of the law which provides for the medical care of the physically handicapped children, we find the Department of Health charged with the following duties:

1. Arrange with all public private hospitals, clinics, and dispensaries and with practicing physicians, to send to the Department of Education prompt and complete reports of any persons under treatment in such hospitals, clinics, or dispensaries, or by such physicians, for injury or disease that may render them physically handicapped.
2. Arrange with health officers to send to the Department of Education prompt and complete reports of any persons who in the course of their official duties they find to be suffering from any injury or disease that may render them physically handicapped, if such persons have not already been reported.
3. Make physical examinations of any persons applying for or reported as needing rehabilitation, except persons reported by the Industrial Commission.
4. Make, within the limits of the appropriations made therefor, physical examination of physically handicapped children who are prospectively or actually incapacitated for the normal pursuit of an education and make recommendations for treatment.
5. On its own initiative or on request of the commission, provide, within the limits of the appropriations made therefor, such surgical, medical or therapeutic treatment or hospital care and necessary appliances and devices for physically handicapped children as in its judgment are needed When the children's court of any county or city whether established under the children's court act or under any special act, shall issue an order for the surgical, medical or therapeutic treatment, hospital care or necessary appliances and devices for any handicapped child, the commissioner of health, if he approves such order, shall issue a certificate to such effect in duplicate, one of which shall be filed with the clerk of the board of supervisors or chief fiscal officer of a city and one in the office of the Commissioner of Health.

The department of health, as will be seen, is directly instructed to cooperate with the Department of Education in locating children who would come under the act, and it is further directed to make physical examination of persons applying for or reported as needing rehabilitation.

It is also instructed to provide, within the limits of the appropriation made therefor, for the medical care of physically handicapped children. The proper procedure for securing the rehabilitation of a physically handicapped child is to have the case presented to the children's court, which will issue an order for rehabilitation based upon the physician's examination and recommendation. This order must be approved by the State Commissioner of Health and, following such approval, the court or the proper representatives should see that the child receives the medical care recommended. The fees and charges incident to such procedure shall be presented by the court or the authority designated to take charge of the child, to the board of supervisors, who shall submit a statement to the Commissioner of Health and receive from the State a sum equal to one-half the amount expended. This procedure is clearly defined in sections No. 1,211 and No. 1,212.

Section No. 1,211 states that one-half of the cost of providing surgical, medical or therapeutic treatment of hospital care and necessary appliances and devices for physically handicapped children as certified by the Commissioner of Health * * * is hereby made a charge against the county or city in case such city has a special children's court act, in which such physically handicapped child resides, and the remaining one-half of the cost thereof shall be paid by the State out of monies appropriated therefor. All claims for services rendered * * * shall be paid in the first instance by the board of supervisors of the county or chief fiscal officer of a city in case such city has a special children's court act, in which such physically handicapped child resides, upon vouchers presented and audited in the same manner as in the case of other claims against the county or city.

Section No. 1,212 * * * states that the clerk of the board of supervisors of each county, or chief fiscal officer of a city of the State * * * which has paid claims as provided herein, shall * * * transmit to the Commissioner of Health, in case the expenditure was made as required by certificate issued by him, a certified statement in the form prescribed by him, stating the amount expended for the purposes specified herein, the date of each expenditure, and the purpose for which it was made. Upon the receipt of such certified statement the Commissioner of Health * * * shall examine the same and if such expenditures were made as required by law, he shall approve it and transmit it to the comptroller for audit.

To us it seems clear that the law intends that the Department of Health shall stimulate local interest in the physically handicapped children, and does not intend that the State shall itself undertake the treatment of such children unless no other way were practicable; and, likewise, we believe that the law intends that when the Commissioner of Health gives his approval to an order of the court, he is certifying that the rehabilitation, whatever it may be, is wisely planned and should be carried out, and it does not intend that he shall make a personal inspection of the bill of fees submitted by physicians or hospital, or both. Such responsibility, in our opinion, rests primarily with the children's court that requested the work and the board of supervisors who audit the accounts and submit the statement to the Commissioner of Health.

The interpretation of this section has been a matter of discussion in certain parts of the State and for that reason we have made a special study of it.

The Public Welfare Law specifically places upon the welfare officer the responsibility of providing medical care for the indigent in his jurisdiction and permits him to decide whether the patient shall be institutionalized or treated at home, with the admonition that "as far as possible families shall be kept together and they shall not be separated for reasons of poverty alone. Whenever practicable, relief and service shall be given a poor person in his own home."

It is the duty of the legislative unit, whether county, city or town, to employ physicians to care for its sick or disabled, and physicians should be very careful to secure authority from the proper welfare officer before they undertake the care of indigents, for which service they expect to be paid. Physicians properly authorized will be paid for their services.

Approval of the proper public welfare officer must always be secured for hospitalization of cases and only "hospitals maintained by the municipality" or "visited, inspected and supervised by the State Department of Social Welfare," can be used.

Therefore, after much study of the laws which provide for the care of the physically handicapped persons and the indigent, we have reached the following conclusions which we offer for your consideration:

1. That the intent of the laws is to have the State assist those who because of some physical or mental infirmity are not able to exercise their full *privileges of citizenship, to remedy or remove such* infirmity;
2. That the State prefers to have such medical care rendered in the homes when practicable and possible, rather than in State or county-provided institutions. Hospitalization for such surgical care is expected and for such purpose the local hospital is to be preferred;
3. That the immediate responsibility for the supervision and conduct of all such work should rest with the proper local body or official;
4. That the welfare officer, when possible, should employ the physician preferred by the indigent;
5. That the State Department of Health, which is authorized to make examination of physically handicapped children, should do so for the purpose of approving or disapproving the recommendations for medical treatment made by the court, but should not express a preference for attending physician or surgeon, nor refuse to honor bills submitted for work performed if charges are commensurate with those generally prevailing in that community;
6. That the State should use its offer of assistance to encourage communities to take financial responsibility of the care of its wards and not to stress clinic work where physicians and hospitals receive no compensation;
7. Every county society should, by resolution, present formal communications to the judge of the children's court and welfare officials, offering the services of the members of the Society.

Your committee, conceiving that its function is literally what its title expresses—that of developing amicable relations with the public—has outlined the following program for future work:

It will seek a conference with representatives of Federated Labor, for the purpose of discussing with the leaders of that large organization the function of the physician in the administration of the workmen's compensation law. We are inclined to feel by the character of bills proposed to the legislature each year that both labor and industry are not adequately evaluating the position of the physician in relation to the injured and incapacitated. Insurance carriers and proprietors of industries, physicians have contended for some time, frequently are not sympathetic with the physician's efforts at rehabilitation.

We have had some contact during the year with another far-reaching organization—The Parent Teachers' Association. We hope to develop a closer relationship with it in the development of a public health program, such as the immunization of children against diphtheria, vaccination against smallpox, etc. A close conference between medical organizations and this group of mothers cannot help but result in profit to the children.

The Farm Bureau and Home Bureau, two powerful organizations in our rural districts, both very progressive and exceedingly well informed on all subjects, have never had the advantages of close relationship with the Medical Society. We are very confident that a more intimate contact with these organizations will be mutually beneficial.

The Chambers of Commerce are wide-awake organizations and every community of any size in the State supports one. All are combined into one State organization and your committee plans to make a contact with this State organization. During the last several years the National Chamber of Commerce has stimulated in local communities an interest in public health conditions and awarded prizes to certain communities where surveys made by the Chamber of Commerce indicate that the health conditions are superior to other comparable communities. It will be our ambition to interest this organization in the practice of medicine as it exists in the communities of the State, as well as in the public health conditions.

The Conference of Mayors, organized some years ago by a prominent physician, has always had a lively interest in public health conditions and the activities of city health officers. The problems of the practicing physician and the advantages a city derives from an active medical organization have never been considered by this Conference and we hope that we can introduce this idea to them.

The Women's clubs of the State, through their Federation and individually, have committees on public health and hygiene and we have occasionally had contact with some of them, but never have we attempted to develop those contacts. This will also be carried in our future program.

The committee is of the opinion that the public has very indefinite and inaccurate knowledge of what the practice of medicine today involves or aims to accomplish. It probably entertains no delusions in regard to the physician's ability and desire to practice curative medicine, but if the magazine articles indicate public opinion, some physicians must be considered unreasonably commercial and hostile to the employment of methods of disease prevention. That such notions should gain widespread acceptance is due in large measuse to two factors: The physician is the first and prime offender in developing and maintaining an exclusive *scientific atmosphere* about himself

and his work, and since we now have specific remedies for some diseases, he is tempted to treat the disease rather than the patient. The second factor has probably been more influential in developing in the public a spirit of impatience with the physicians. Science daily gives the public some new observation of fact relating to physical welfare and happiness. Most of these have real news value and are heralded far and wide They are usually adopted by some group which, for its own advantage, exploits them upon the public until they become fads. The public usually knows more than the physician about the advertised virtues of these fads and gradually it has come to believe the physician is purposely unfriendly to the propagation of these new ideas.

If the physician and the everyday public could only sit down together and talk over their points of view, we are convinced the misunderstandings would be eliminated and the propagandist would be obliged to leave the domain of health.

Your committee, with full realization of the enormity of the task, nevertheless has outlined a program in which it will play the role of ambassador to the public; or, stated in the language of the street, we hope to "sell medicine" to the public through its organized units.

The committee wishes to express its appreciation to Dr. Joseph S. Lawrence, Executive Officer, for his active cooperation and service in the interest of the work of the committee. Without his aid and almost continuous help it would have been impossible to have carried on this work to the extent that it has.

It also desires to express its appreciation for the publicity given the work of this committee by the NEW YORK STATE JOURNAL OF MEDICINE. The Publication Committee and Editors have been most generous in their allotment of space to all matters relating to the activities of this committee.

Respectfully submitted,

JAMES E. SADLIER,
Chairman,

April 15, 1931.

REPORT OF THE COMMITTEE ON ARRANGEMENTS

To the House of Delegates.

Gentlemen:

The Committee on Arrangements desire to report the following:

The tenth floor of the Hotel Syracuse has been reserved for the meeting of the Medical Society of the State of New York from June 1st to June 3rd inclusive. On this floor will be the registration booth, the meeting for the House of Delegates, the general banquet, all scientific and commercial exhibits and the meetings for the scientific sections with the following exceptions:

(1) The section on Surgery Tuesday morning will be held on the Roof Garden of the Onondaga Hotel.

(2) All sections of Obstetrics and Gynecology will be held on the second floor of Huntington Hall which is one block from the hotel.

(3) Physical Therapy Session will meet at Huntington Hall on the first floor.

(4) Public Health and Hygiene sections will meet in the West Memorial Chapel of the Mizpah.

The banquet will be held on Tuesday evening, June 2nd. There will be a varied entertainment of an excellent character, mainly amateur. The main feature will be an address entitled "Comings and Goings" and will be delivered by T. Wingate Todd, Professor of Anatomy at Western Reserve School of Medicine in Cleveland. Dr. Todd is an anthropologist of note. His addresses are intensely interesting and, in particular, entertaining. Those, who have heard him, say they will never miss hearing him again if given the opportunity.

It is desirable that the out-of-town members purchase their tickets for the Tuesday evening banquet as soon as possible so that necessary arrangements can be confirmed. Tickets may be purchased from Dr. F. S. Wetherell, Chairman of the Banquet Committee, 713 E. Genesee Street, Syracuse.

The various hotels in Syracuse have all signified their willingness to give you their best service.

Any members desiring to play golf can do so by communicating with the Chairman of the Committee on Arrangements.

The Women's Entertainment Committee are planning a garden party on June 2nd, from three to five o'clock at the home of Mrs. Carl Muench, Rocky Dunes, Fayetteville; cars will be provided. Those wishing to attend, meet in the lobby of the Syracuse Hotel, at 2:30 P. M.

On June 3rd a luncheon will be held at Drumlins Country Club at one o'clock. Those who desire may remain and play bridge or be driven about the city in cars which will be provided. Those wishing to attend the luncheon meet in the lobby of the Syracuse Hotel at 12 noon.

Respectfully submitted,

FREDERICK H. FLAHERTY,
Chairman.

April 15, 1931.

REPORT OF THE COMMITTEE ON LEGISLATION

To the House of Delegates:

Gentlemen:

Another anxious and eventful legislative session has just closed and the staff of the Legislative Bureau of the Medical Society of the State of New York are on the verge of nervous exhaustion from the anxiety of imminent defeat. Again the Osteopathic and Chiropractic bills came very very near passing the legislature. I feel certain that unless the medical profession take some positive action these and other similar bills will become laws in the near future.

What is the Medical Society of the State of New York going to do about it? What are you going to do about it? Are you going to continue to delegate this important function to the few members of the County and State Legislative Committees or are you going to take a personal interest in the matter and see what can be done about it?

Unless our policy of purely active or passive resistance is changed we are bound to be beaten. No contest in history has ever been decisively won by a purely defensive attitude. Any privilege worth having has always been coveted by outside groups and unless the possessors were willing to do more than simply resist they were invariably worn out and defeated by constant and repeated attacks. Only a few years ago, in a weak moment, the osteopaths and physiotherapists "broke in" and it was not long before they imitated the proverbial camel. Other groups are waiting at the door.

The practice of medicine is undergoing a most radical change. At the same time we are being attacked on all sides by our everlasting enemies, ignorance, quackery and charlatanism, which combined in various cults are ever hungry for the prey—the gullible, sick public. Some of our so-called friends, the welfare organizations, are doing us irreparable harm by their constant encroachment on our legitimate field of work.

The first skirmish of any coming attack is usually a bill introduced in the legislature under some plausible excuse or in the guise of some well-meaning purpose. Under the circumstances, the legislative committees (County and State) are our first line of defense. They must be well organized, present a united front, and must be in intimate contact with the rest of the medical profession so that in case of danger every member may be called upon to aid in its defense. Theoretically, we have some such organization. Practically, we have nothing of the sort.

"ORGANIZATION—CONTACT—SUPPORT"

Our organization is seriously defective in several important phases. Few, if any, of our county legislative chairmen are in direct contact with their respective Comitia Minora and the general membership. While our opponents are usually pouring in thousands of letters and telegrams into the legislative chambers, the general medical profession outside of the legislative committees is rarely heard from. The medical profession as a body knows very little of what is going on in the legislature during the most important and critical period—the last two weeks, and there is no way at present in which the legislative committee can reach the general profession during the last few days of the session—a contact which is almost vital.

RECOMMENDATION

Each and every County Society should establish a direct contact between the chairman of the legislative committee and the membership, through its Secretary.

In case of emergency the chairman of the county legislative committee should be given the power to call directly on the membership for letters, telegrams or telephones to the legislators at the expense of the Society.

ORGANIZATION—POLITICAL

In the course of their professional work, the doctors come in contact directly or indirectly with nearly every voter in the State, within a fortnight. Leaders of both political parties have told me that *potentially* the medical profession is the most powerful political group in the State. *Actually* they are considered of no importance politically because of their well known antipathy to politics and their individualism. In the present critical situation in the practice of medicine it is urgent that we organize, not to meddle with politics, but to make every effort to prevent the renomination and election of a legislator who by his action has shown himself hostile to the welfare of our group.

RECOMMENDATION

That each and every County Society study the records of their respective legislators in relation to the practice of medicine and take effective action through the local press and personal propaganda to prevent the renomination and election of those who are avowedly hostile to their interest.

"A UNITED FRONT"

The necessity of a united front for any effective action is so self evident as to require no explanation. The State Legislative Committee is ever ready and anxious to consult or confer with any medical group on matters of legislation. The main function of the State Committee is advisory and executory. It simply carries out the wish of the majority where such a wish has been expressed and advises the Executive Officer as to the best procedure where the wish of the majorities is not known. This Committee has often been embarrassed and dismayed by individual actions of County Societies, who, without consulting either

the State Officers or the Committee, have gone directly to the legislature. Take for example our experience of last winter.

The House of Delegates by a unanimous vote at two sessions ordered the State Committee to introduce a certain bill. Before the bill was prepared (early last January) and without consulting the Legislative Committee, one of our counties protested to the members of the legislature. Such action does irreparable damage to the prestige of the State Medical Society at Albany without accomplishing anything.

RECOMMENDATION

That the House of Delegates call the attention of the County Societies that as members of the State Society it is their duty to abide by the decision of the House of Delegates, and the House of Delegates instruct County Societies that all matters of legislation be transacted through the State Legislative Committee.

For a number of years two facts have rankled in my mind until I find it difficult to give them calm expression.

1. For years the medical profession has been fighting the fight of the public against medical inefficience, fraud and charlatanism. The actual financial loss to the individual physician from the admission of chiropractor to practice or the permission of untrained men to perform surgery would be too small to merit consideration. The danger to the public from the spread of contagious disease, neglected cases of tuberculosis and cancer, etc., is great. Our representatives in Albany are not only unconscious of the fact, but actually suspicious of our activities and ready to believe that our motives are selfish, low and sordid.

2. Modern medicine has eliminated most of the dread diseases. It has saved millions of lives and has prolonged the lives of millions of others. Medicine is taught as a recognized science in all the highest universities of the world. Before a man is permitted to practice medicine he must go through a preliminary course of education at high school and college and a most thorough course of preparation. In the halls of our legislature he stands no higher and is considered no better than a *chiropractor*.

RECOMMENDATIONS

1. That a committee consisting of members of the State Society and the Academies of Buffalo, New York, Rochester, Syracuse and Utica be appointed whose duties it shall be to acquaint the public by well prepared, *repeated* publicity—that it is to the public's vital interest to see that the practice of medicine is kept at the highest possible level, that the public should be more concerned in keeping out the quack and unfit than the medical profession, and that organized medicine is tired of fighting the public's fight single handed.

2. That a committee consisting of members of the State Society and the Academies of Buffalo, New York, Rochester, Syracuse and Utica be appointed whose duty is shall be to urge the following proposition on the presidents and faculties of the great universities of the State of New York.

If there is a grain of scientific truth in the theory of chiropractic, it is their duty to teach it. If, on the other hand, chiropractic is a fraud and has no foundation in truth, then it is the duty of the said universities to their respective communities and the people of the state—to come out and say so.

That the universities be urged to appoint a group of *non-medical* scientists to investigate and report on the theories and practice of chiropractic, and that, if necessary, the medical profession pay for the expense of the investigation.

Although more bills (4312) were submitted to the legislature this year than last, a slightly fewer number of them (126) had a bearing upon the practice of medicine and, therefore, a direct interest for us. On the other hand, this has been the most difficult legislative year we have had for some time. This opinion is not ours alone, but has been expressed by representatives of other organizations and even by certain officers of the legislature.

We had the usual number of objectionable bills to combat, but for certain reasons over which we could exercise no control, some of them were much more troublesome than in previous years. For a while the sentiment in the Education Committee of the Assembly seemed to be strongly against advancing either the chiropractic, the osteopathic or the physiotherapy bills. However, when it closed its business it only defeated the physiotherapists' bill.

The osteopathic bill was the first of these bills to be voted upon by the legislature and passed the Senate with only seven negative votes, but was defeated in the Assembly by a vote of 55 to 81 and laid on the table. On the last day of the session an effort was made to take it from the table, but was not successful, lacking one vote of the necessary 76.

The chiropractic bill passed the Assembly by a vote of 78 to 57, but in the Senate could muster only 12 votes in its support. More personal canvassing of the legislators for support of these bills was conducted this year than in previous years.

Several bills providing for free choice of medical care by the injured workman were introduced by representatives of both political parties, but all met the same fate; they were killed in the Labor Committees. A greater number of bills were introduced providing that each and every disabling condition arising out of occupation should be compensable than in any previous year, but all were defeated in the Labor Committees.

The Wicks-Hutchinson bill which arose from the report submitted by the Governor's Special Health Commission, met with some opposition and was amended so as to carry these several features—the erection of three state tuberculosis hospitals and an amendment to the law regarding the treatment of venereal diseases. It also provides for the creation in the Department of Health of two divisions; namely, a division of orthopedics and a division of cancer control. Another portion of the original Wicks-Hutchinson bill was drafted into a new bill, but was not reported favorably by the committee. This bill contained, among other things, a statement of the function of the Public Health Council regarding the approval of public health work and the establishment of qualifications for public health employees. Discussion of this bill by some legislators indicated that there is a feeling that the legislature should not delegate so freely to State Departments the right to frame rules and regulations that have the force of law. Before laws can be enacted by the legislature they are subjected to considerable publicity and opportunity is accorded citizens of the state to argue before the legislature the worth of the proposed laws. State Departments do not accord the public the same privilege with regard to the rules and regulations they draft and enact. This argument appeals to us and we present for the consideration of the House of Delegates the following proposition to form the basis of an amendment to the law:

RECOMMENDATION

That in the future the Public Health Council shall cause to be printed in "Health News" all proposed rules and regulations and modifications of the sanitary code. Before any such rules, regulations and modifications shall be adopted, the Public Health Council shall announce not less than ten days in advance of the hearing a place and date not less than one month subsequent to the first publication of the proposed measures, where it will hear those who may have objections to the proposed measures.

This would afford the public an opportunity to assist the Public Health Council in framing the laws by which our public health is administered. We feel that a similar provision should be made with regard to the enactment of the sanitary code in New York City. We feel quite confident that the legislature would heartily endorse a proposition of this character and we believe it to be in the interest of the public that it should be adopted.

The bill providing that in cities of more than 50,000 health officers appointed in the future shall be obliged to devote their entire time to the office, had an uneventful career, passing through both houses with no opposition and the bill now rests with the Governor.

Acting as directed by your body last year, we, through the Executive Officer, sought a conference with the Commissioner of Labor, for the purpose of redrafting the bill providing for the creation of a medical advisory council in the Department of Labor, but met with indifferent success. We wrote to the Commissioner on November 8th, asking for a conference, but received no reply. We spoke with her twice on the telephone and finally called upon her when she was in the Capitol. She frankly stated that she did not want a medical advisory council created and suggested that the matter be brought before the commission appointed by the Governor to review medical and surgical problems in connection with the workmen's compensation law. Realizing that no bill could pass if she opposed it, we accepted her suggestion.

Again our relations with the legislature were very cordial. We were frequently asked to discuss proposed health measures by individuals and before committees.

We are particularly happy to report that the county chairmen afforded us greater aid this year than in any previous year. Probably their greater cooperation is due in part to the interest aroused by the conference of chairmen which was held in Albany on February 10th. Thirty-three counties were represented at that conference. Our suggestions to the chairmen at intervals, asking them to communicate with their legislators, have been very generally followed out. We have had abundant proof of this from the legislators themselves. The prompt and hearty support received from those chairmen appealed to, the night before the chiropractic bill was voted upon in the Senate, must have had a great deal to do in determining the character of that vote.

Respectfully submitted,

HARRY ARANOW, *Chairman.*

April 20, 1931.

REPORT OF THE COMMITTEE ON MEDICAL ECONOMICS

To the House of Delegates—
Gentlemen:

The Committee on Medical Economics of the Medical Society of the State of New York is composed of the following physicians:

Drs. George F. Chandler Chairman, Edgar A. Vander Veer, Edwin MacDonald Stanton, William L. Bradley and John L. Bauer.

By arrangement with proper authorities the sum of twenty-five hundred dollars was set aside by the State Medical Society for use of this Committee.

A file was purchased which is the property of the State Medical Society to be turned over to them June 1, 1931. The correspondence stationery has been furnished the Committee from the headquarters of the State Society. Accounting of all moneys expended has been transmitted to the Treasurer of the State Society including postage, long and short distance telephoning, printing, stamped envelopes, salary of Miss Conway as Secretary and ten girls as clerical workers, as communications have been sent to every physician who is a member of the State Society.

The Committee after deliberation felt that matters incident to the medical and surgical care of employees in connection with the Workmen's Compensation Law were most pressing and the greater part of its time was spent on this matter.

Bulletins were issued to County Societies.

Letters were written to the Milbank Fund, to the State Charities Aid Association and to the Department of Health of the State of New York for reports as to their activities. It was felt that this was advisable because it would let such organizations know that their activities were being scrutinized by organized medicine.

The compensation matter which in toto represents the expenditure of forty millions of dollars a year in the State of New York of which from nine to twelve millions go for the medical and surgical care of patients, was such an involved proposition that it is impossible to give in a short report the procedure, the trials, the number of meetings, the conferences and all of the activities incident to the consummation of the plan that has been put in motion. Copies of letters sent County Societies, Agreement and Fee Schedule are as follows and are self-explanatory:

To the Secretary of .....
County Medical Society.

1. Will you kindly at the November meeting of your Society, or at a special meeting, bring the matter of the enclosed agreement between your Medical Society and the Compensation Carriers up for action through the Economic Committee of your County Society?

2. It is necessary that such agreement be completed within the month of November.

3. It is the earnest desire of the State Economic Committee that favorable action be taken upon this agreement between each County Medical Society and the Compensation Carriers.

4. We expect that this agreement will be very quickly consummated between the five counties comprising the Metropolitan District and the 80 or 90 Insurance Carriers, and this means that about 10,000 physicians in the State are favorably inclined. The State Economic Committee wishing all of the Counties to have the benefit of this agreement are forwarding copies to each County Society so that the remaining four or five thousand physicians may be benefited.

5. Practically all of the Insurance Carriers will be in agreement and this will mean that any case can be treated by any reputable member of the State Medical Society without authorization by the Insurance Carrier; that a board of arbitration consisting of two members from the Insurance Carriers and two physicians who are members of the County Society properly designated shall be the last word in adjustment of bills and other matters.

Should this agreement be mutually accepted, it will accomplish what has been in the minds of physicians for many years. It is a gentlemen's agreement, can be given a trial and later on if there are some things to be taken up, such as the matter of proper fees, they can be easily adjusted. It is to be noted that it will not be necessary to have any legislation, and we of the State Economic Committee have been given assurance that it is looked upon with favor by the Industrial Commissioner and the representatives of organized labor.

Again may we request that this be acted upon immediately and that the agreement be signed and forwarded to the Chairman of the Committee on Medical Economics.

Dear Doctor:

Enclosed find tentative agreement as formulated by the Committee on Medical Economics of the Medical Society of the State of New York and insurance carriers.

You will note that this agreement is between the separate county medical societies and the carriers. It is a voluntary agreement on the part of both parties and is designated primarily to furnish a means whereby the family physician and general practitioner may treat compensation cases without authorization and can play his part in rendering the best care in cases of industrial disease or injury.

Copy of a fee schedule is herewith enclosed. This fee schedule is understood to represent a working basis for charges. It has been formu-

lated on a flat rate, full treatment plan with the idea of offering full remuneration for results obtained irrespective of the number of office calls and details of treatment. It is believed that the rather high fees allowed will be justified by the absence of any incentive to multiply the number of calls.

You will note that provision for consultations, *x*-rays, and all forms of therapy are provided for.

It is urgently requested that physicians will endeavor to fill out C-4 forms within the first week after assuming medical or surgical care of an employee.

The plan is such that improvements can be made from time to time.

Arbitration Boards are being formed in central locations throughout the State consisting of two representatives designated by a county medical society and two representatives designated by the insurance carriers.

Should difficulties arise, get in communication with the chairman of the committee on medical economics of the County Medical Society of which you are a member.

STATEMENT OF PRINCIPLES AND AGREEMENTS BETWEEN THE MEDICAL SOCIETY OF THE COUNTY OF ..... AND THE COMPENSATION CARRIERS COMPRISING THE STOCK COMPANIES, MUTUAL COMPANIES, STATE FUND AND SELF-ASSURED

STATEMENT OF AIMS

The aims of the County Medical Society are

To secure for its members the acquiescence of the carriers to recognition in treatment of compensation claimants by those physicians who fall within the definition as hereinafter more fully set forth without formal authorization from employers.

The aims of the Carriers are

1. To receive the cooperation of the County Medical Society and its members in the interests of a proper administration of the Workmen's Compensation Law from the standpoint of the employee, to wit: That the employee receive skillful medical and surgical care; that the necessary forms be promptly completed so that the carriers will be able to promptly pay compensation, and that the necessary forms be quickly filed; in the desire of securing reasonable and prompt bills for services rendered to employees by the medical profession, and that the bills and forms be forwarded to the companies and not to the Compensation Commission as has been done in the past by some physicians who have been uninformed.
2. To express in words the present practice of reputable carriers and remove from the minds of the medical profession the existing erroneous opinion that the carriers indiscriminately and captiously lift cases of injured employees from the care of competent and qualified family physicians of those employees.

Thus, in correspondence with the preamble the following agreements are entered into:

1. The County Medical Society will use every reasonable effort to impress upon its members the importance of careful and skillful treatment of industrial injury and occupational disease cases, and bring home to its members the thought that the chief principle in treating these cases is that the injured employee be brought back as quickly and fully as possible to as near an efficient and economic person as is possible.

   In line with this the County Medical Society will urge upon its members that if cases reach them in which the physician is not entirely sure that he is, by training and experience, capable of handling, the doctor will immediately communicate with the carrier for advice.
2. The County Medical Society further agrees that it will impress upon its member, and secure from its members, an agreement to complete the necessary paper work, or forms, such as C-4 or C-5 and other forms, within one week in each case, and that these forms will be promptly sent to the carriers; that on these forms will be furnished such information as the physician has at the time of completing the form, and that the physician will furnish such other reasonable supplementary information as requested; and, finally, will submit promptly an itemized, self-explanatory bill for services rendered.
3. The County Medical Society of.....will evolve from time to time fee schedules, and submit them to carriers for approval, for service rendered to injured employees, and will call upon its members to conform to such fee schedules, it being clearly understood that this fee schedule shall be a guide to the treating physician in the preparation of his bill for services.
4. The Medical Society of the County of..... further agrees that it will participate in the creation of a joint committee of physicians and carriers to act as an Arbitration Board, for the settlement of disputed bills between physicians and carriers. This Committee shall consist of two members of the County Medical Society and two representatives of the carriers. No arbitrator shall sit in any case in which he or the party he represents is interested. Any physician submitting to arbitration shall abide by the decision of the Board.

   The County Medical Society will expect its members to present all cases of disputed bills to the Arbitration Board as above stated for prompt action.
5. The members of the County Medical Society agree to seek the advice and abide by the decision of the carriers as respects consultations, X-rays, physical therapy and other treatments beyond ordinary treatments, and, further, the physicians will cooperate with representatives of the carriers in securing for the carriers examinations of claimants at reasonable times.

   Although the members of the County Medical Society shall generally adhere to the above stated principle, still in emergency cases where, in the opinion of the attending physician, the welfare of the patient demands, and the protection of the physician requires, an immediate consultation or X-ray, it is understood that the physician shall proceed properly and the question of the necessity of such action and the reasonableness of the charges incurred, if disputed, shall be passed upon by the Arbitration Board.
6. The County Medical Society agrees to hold meetings at which such physicians as are specialists in industrial medicine and surgery may appear to discuss improved phases of this work, and will further provide meetings at which persons familiar with the operation of the Workmen's Compensation Law may appear and inform the members of the Society in respect to the detail matters necessary to the proper carrying out of the compensation laws.

7. The County Medical Society agrees to develop and establish standards both of equipment and training for physical therapy and X-ray. After such standards have been arrived at, the County Medical Society will expect its members to comply therewith.

1. The carriers agree that when they participate in the Arbitration plan, as set forth above and present disputed bills for services between the carriers and physicians who are members of the County Medical Society, they will abide by the decisions of the Board.
2. Carriers agree to participate with the County Medical Society in setting up and adhering to the fee schedule.
3. The carriers agree to waive the question of authorization for family physicians who are members of the County Medical Society and who will comply fully with the agreed plan of the County Medical Society and the carriers. Reasonable charges for services of such physicians will be promptly paid.
4. The carriers agree to furnish literature, as may be available and take other measures to aid in instructing the members of the County Medical Society in relation to the industrial medical and surgical fields, and also with regard to the detail and paper work which is so important a feature in the efficient administration of the Workmen's Compensation laws.

Letter forwarded to the Chairman of the Medical Economic Committee in each County Society through the secretary of each County Medical Society so that physicians may understand the procedure necessary in the arbitration of difficulties arising in connection with the medical and surgical treatment of cases incident to the Workmen's Compensation Law in the State of New York.

Enclosed are copies of (a) the Arbitration Agreement (b) Doctor's statement of case and (c) Carrier's statement of case.

These forms are to be used in connection with the arbitration of medical and surgical cases incident to the Workmen's Compensation Law in the State of New York. Arbitration Boards throughout the State are being set up at designated points based upon the experience of the Board that is functioning in New York City.

In the event that a physician desires to arbitrate a matter he should notify the chairman of the Economic Committee of his County Medical Society of this fact. Upon receipt of such notice, the Chairman of the Economic Committee of this County Medical Society will send the physician wishing to arbitrate, a copy of the blank headed "Doctor's statement of case." The doctor shall then fill out this blank and attach detail copies of all bills in connection with his case and then return it to the Chairman of the Committee on Medical Economics of his County Society. The County Chairman of the Committee on Medical Economics will then forward the completed doctor's statement of case to Mr. William P. Cavanaugh of the National Bureau of Casualty & Surety Underwriters, 1 Park Avenue, New York City, who will immediately notify the Company involved and secure a statement of the case from them. Shortly after this, arbitrators will be selected and the matter will be placed upon the Arbitration calendar for hearing. Both the physician desiring to arbitrate and the insurance company will be notified of the time and place of hearing which will be arranged conveniently for both parties. They will then appear and present such witnesses as they see fit.

If, the County Medical Economic Committees have not been formed, or for one reason or another such committee is not functioning, the secretary of the County Medical Society can attend to this matter instead of handling it through the Economic Committee.

Fee schedule as basis of charges in connection with the Workmen's Compensation Law as suggested by a committee of insurance carriers and the committee on Medical Economics of the Medical Society of the State of New York.

EXPLANATIONS

The charges listed in this fee schedule are flat rate, full treatment charges and unless otherwise arranged for by the carrier shall include all treatment ordinarily furnished by the surgeon and his assistants. The fees as listed do not include hospital charges, or charges for X-rays, anaesthetics or special laboratory examinations. Extra charges for physiotherapy and other forms of special treatment shall be made only when sanctioned by the carrier for the individual case.

The rate for compound fractures shall be 50% greater than for simple fractures, and in cases in which dressings are required after three weeks extra charge of $2 per dressing can be made.

Amputations—

Arm	$ 75
Forearm or hand at wrist	75
Arm at elbow joint	75
Arm at shoulder	150
Foot	75
Foot between ankle and tarsal joint	100
Leg at knee joint	100
Thigh between hip and knee	100
Thigh at hip joint	150
Finger or toe	25
Fingers or toes	50
Finger or toes distal to last phalangeal joint	25
Fingers or toes 2 or more, to last phalangeal joint	50

Excisions—

Shoulder, hip, knee, elbow, wrist—same as amputations.

Fractures—

Humerus	$100
Elbow joint	100
Ulna and radius	75
Ulna or radius	50
Colles'	50
Femur	125
Patella	75
Tibia into knee joint	100
Fibula above ankle joint	25
Tibia	75
Tibia and fibula	75
Potts	75
Hand, to include carpal and metacarpal	25
Finger	20
Great toe	30
Small toes	15

Tarsal, Metatarsal	50
Jaw—by surgeon or dentist-surgeon	50
Ribs, one or more	25

(In case of extensive injuries additional charges relative to seriousness of injury).

Pelvis	75-150
Spine with cord involvement	200

The charge for fractured spine with cord involvement does not include late neurological treatment.

Spine, cord not involved	100
Spine, transverse processes only	50
Nose with deformity	25
Clavicle	50
Scapula	50
Skull—non-operative	30
Skull—operative	100
Skull—severe types, non-operative	50

Dislocations—

Shoulder	$ 35
Elbow	35
Wrist	35
Hip	50
Knee	75
Ankle	50
Spine with paralysis	150
Finger or toe	15

Special Operations—

Laparotomy	$125
Chest (op. wall or contents)	100
Hernia, single	75
Hernia, double, if ordered by Carrier	100
Injury to urethra, perineum or bladder depending on severity	10-100
Prophylactic injection tetanus anti-toxin	5
Incision for abscess	5
Incisions for more extensive infections	25
Lacerations of soft tissues requiring operation with no anaesthetic	10-15
Lacerations of soft tissues requiring anaesthetic	10-25

In case of wounds requiring numerous dressings, additional charges for dressings can be made after two weeks.

Medical—

First aid, or single office call including C4	$5
Office calls—after first call	2.50
Office call with dressing of infection	3.50
House call—day	3
House call—night	4
Hospital call	3
Office (specialists)	3-5

Special Items—

Baking or high frequency (Including office call)	$ 3
X-rays 5x7	5
X-rays 10x12	7
X-rays 11x14	8
X-rays 8x10	6
X-rays 14x17	10
Stereoscopic	50% extra
Fluoroscopic	5
Consultation	10
Examination in lunacy written report	10
Complete physical examination	5
Autopsy with report written	50
Autopsy, attending not performing	10
Introducing catheter	5
Attendance and testimony as to fact before Commission	15

Testimony as expert witness to be arranged with Carrier.

Before June first these same fee schedules will be in the hands of the Supervisors of each County so that they may have a working idea of the proper fees to expect under the new Welfare Law in the care of County cases. Already they are in the hands of the Secretaries of each County Medical Societies who are forwarding them to the Supervisors of their Counties.

You will note that the agreement and the whole machinery of the comprehensive plan of Arbitration Boards and fee schedule are made between the separate County Medical Societies of the State of New York and the insurance carriers through the activities of the Economic Committee so that the State Society as such is not committed. It is a mutual agreement without legislation and can be tried out on the same principle as the trying out of improvements in machinery in the laboratory for it is an earnest effort to clarify this much disputed question of the exchange of moneys between the employer and the doctor.

After it is in operation if there are any faults they can be easily cleared up and then possibly from this laboratory experiment, if I may call it such, legislation may be forthcoming if necessary.

We of the Committee felt that there would be in some quarters a certain amount of opposition to a plan which involved a fee schedule but we also felt that no progress could be made unless some individual or group of individuals was willing to take the responsibility for an earnest trial to better existing conditions.

The fee schedule after long deliberation we consider liberal but honest and no improvement could be made without some financial standard as a working basis. The Committee therefore assumes full responsibility in this matter hoping that the results will be more than a gesture and will accrue to the advantage of both employer and employee with the ultimate result that the doctor will be paid a fair amount for his services and the employee will get the best medical and surgical treatment, and this to be done by the family doctor without designation.

The Committee feels that it cannot make its report without special reference to the invaluable help it received from Dr. Morris Rosenthal, Chairman of the Committee on Economics of the Medical Society of the County of New York. He was untiring, and many of the fundamentals of the mutual agreement between the insurance carriers and the county societies originated with him.

There are other matters for this Committee but the work entailed in the compensation law has been so tremendous that very little else could be given attention.

Respectfully submitted,

GEORGE F. CHANDLER, *Chairman.*

April 15, 1931.

REPORT OF THE COMMITTEE ON SCIENTIFIC WORK

To the House of Delegates—
Gentlemen:

The Committee on Scientific Work has held three meetings, the first in Albany on October 15th, the second in New York City on December 11th, and the final one in Syracuse on March 8th. At the last conference the section rooms were investigated and, through the cooperation of the local Committee on Arrangements, we expect every one to be housed in a most satisfactory way.

The Scientific Program will follow the plan inaugurated last year, that is Tuesday and Wednesday morning will be given over to Section meetings and the afternoons will be devoted to the special consideration of major problems.

The Tuesday afternoon assembly will be opened with an address by William Gerry Morgan, M.D., Washington, D. C., President of the American Medical Association. This will be followed by a Symposium on Psychopathology and Psychotherapy under the leadership of Dr. Smith Ely Jelliffe with the cooperation of Dr. Frankwood Williams and Dr. Abraham Brill. This will give all members of the Society an opportunity to meet together and hear a modern exposition on this increasingly important division of medicine.

Wednesday afternoon a Symposium on Head Injuries will be presented in a popular way by Dr. Wells P. Eagleton of Newark N. J., Dr. Albert G. Swift and Dr. Foster Kennedy. Your Committee is convinced that the subject is of vital interest to every physician because of the increasing number of serious automobile accidents.

Each section chairman has arranged a most attractive program. Several speakers from other states will be present to deliver talks and join in the discussion. Many papers will be illustrated with lantern slides and some moving picture demonstrations will be staged.

Your Committee has had great difficulty in arranging an instructive program because of the conflict between our meeting and that of many of the special societies. We most respectfully suggest that, if possible, our annual meeting be held at a time when the leaders of medical thought are not obligated to attend their special societies.

The Chairman of the Scientific Committee has received the hearty support and cooperation of the members of his Committee and it affords him great pleasure to acknowledge his indebtedness to them.

Respectfully submitted,
ARTHUR J. BEDELL, *Chairman.*
April 15, 1931.

REPORT OF THE COMMITTEE ON MEDICAL RESEARCH

To the House of Delegates—
Gentlemen:

In behalf of your Committee on Medical Research I have the honor to present the following report:

Two matters have engaged the attention of your Committee. The bill to exempt the dog from all experimentation which was introduced into the Federal Congress, and referred to the Committee on the District of Columbia, was opposed by all the organized medical bodies of the United States. Your Committee took formal action in the way of letters to the representatives of New York State in Washington. Our objections to this bill were also presented in less formal but perhaps more effective ways.

The second occasion to engage the attention of your Committee was the introduction into the Assembly of the State Legislature of the perennial Vaughan bill to exempt the dog from all experimentation. A hearing was held by the Committee on Codes on February 24, 1931. Your chairman wishes to acknowledge the active support given by the institutions most concerned in the direction of medical teaching. Those who appeared were: Dr. Hartwell, President of the New York Academy of Medicine; Dr. Wadsworth, of the New York State Department of Health; Dr. Robinson, Director of the New York Hospital Cornell Medical College Association; Dr. Wyckoff, Secretary of the New York University and Bellevue Medical College, also representing the Tuberculosis and Heart Association; Dr. Rous, of the Rockefeller Institute, Associate Editor of the Journal of Experimental Medicine; Dr. Horatio Williams of the College of Physicians and Surgeons of Columbia University; Dr. Gerster of the Association for the Control of Cancer; Dr. Stanton of Schenectady; Dr. Schiff of the Laboratory Association. Dr. Morton of the University of Rochester was prevented by illness from attending.

No official report of the action of the Committee on Codes has been received.

Respectfully submitted,
JOSHUA E. SWEET, *Chairman.*
April 15, 1931

REPORT OF THE COMMITTEE ON PERIODIC HEALTH EXAMINATIONS

To the House of Delegates:

Gentlemen:

I have the honor to present the annual report of the Chairman of the Committee on Periodic Health Examinations.

The first year's work of the Committee was devoted to the formulation of a policy and a procedure. This involved primarily the application of medicine as a science to a practical service. On the scientific side, it was recognized that the field of preclinical medicine was new. It required stimulation. But most of all, it needed wise beginnings to avoid later correction. The health examination, on its practical side, had to be adapted to the several and diverse needs of children, adults, men, women, workers in industry, teachers in schools, farmers, fathers, mothers, etc. It was a procedure which should be adjusted to greatly varied conditions of age, occupation, sex and circumstance.

In addition to its integrity as a scientific procedure and its diversity as a practical measure, the health examination has a reciprocal bearing upon organized medicine, the body politic, the official organizations of the state, nation, city and county, and the great groups of men and women organized in membership societies, in insurance companies, to say nothing of the social and philanthropic organizations touching upon the field. In addition, the organization and progress of this movement are a part of the organization and progress of the Medical Society of the State of New York, and its operation has proceeded harmoniously with the several Committees, to wit, on Public Relations, Medical Economics, Public Health and Medical Education, and Legislation. All this was reflected in the report rendered to the House of Delegates a year ago.

The resolutions of the House of Delegates on our recommendations gave to the Committee approval, direction and encouragement, and provided in effect, a charter on which it proceeded to work. This year has been devoted to that work. Whereas, the first year was largely a survey of the field of operation, this year has been one of labor in plowing and planting in this field. While a continuing harvest is prepared for and is in prospect, there are some results which have already been attained.

The objective of the Committee is, "The health examination of all of the citizens of the State of New York," conducted primarily in the office of the private physician. This result is not to be attained in a short time. Progress toward this end involves first, the bringing of the public to the physician's office, and second, the provision of a good and satisfactory examination. This report will omit the many phases of the work which have been given in detail in the monthly reports, the minutes of the Committee meetings, and the articles which have been published in the Journal during the current year, and will confine itself to a very few of the more important matters in progress.

I. *For the Physician—*

A. To aid the physician in giving addresses on Health Examinations to lay audiences, a series of suggestions has been prepared by the Committee and is about to be published in the NEW YORK STATE JOURNAL OF MEDICINE. This gives a clear picture of the fundamentals of the subject, avoids heresy, and provides workmanlike methods of presentation. This is prepared primarily to help physicians giving addresses to the women's groups in connection with the drive for health examinations conducted by the New York State Federation of Women's Clubs in cooperation with our Society.

B. In connection with the continuing effort of the Federation of Women's Clubs and other women's organizations, it is proposed to provide for our members medical information especially designed to aid them in conducting health examinations for women. To this end, there is presented the following, so that the members of the Society may contribute their best professional efforts to this movement.

A Selected List of Topics for a Series of Medical Articles and Addresses on the Subject of the Health Examination of Women

It is proposed that these shall be submitted to the Journal, reprinted, collected, and perhaps published in a single volume. Members of the Medical Society of the State of New York are invited to submit manuscripts to the Committee for publication

A. Special problems according to Age Period, such as:
   1. The Menopause and the menopause period.
   2. The woman of 60.
   3. The young matron and her personal health.
   4. Premarital health examination.
   5. The college women's health problems and health examination.
   6. The high school girl's health examination in school or in the physician's office.
   7. The prepubertal period in the young girl and its relation to school, the home and medical guidance.

B. Special problems relating to Special Status.
   1. What is practical in the health examination of the woman in the village and small town.
   2. Industrial health examinations for women. Their aims and limitations.
   3. Health Exhibitions and Health Contests at County Fairs.
   4. The Y.W.C.A. program and the neighborhood physician.
   5. What the Girl Scouts are doing for health from the standpoint of the practising physician (also Camp Fire Girls, and Girl Reserves, 4 H Clubs.)
   6. The Health Examination of women in institutions, state and private.

7. Trade unions and the health examination.

C. Special problems relating to special regions of the body or to special diseases, not only the contribution of the specialist to the information of the general practitioner, but the viewpoint of the health examiner on his own problems. This should include:

1. A simple practical method of examining the part or the system.
2. A statement of the commonest findings, not the rare, peculiar and exciting.
3. A simple statement of what to do and how to do it, i.e., the first prescription which informs, motivates and carries forward further diagnosis, care, treatment in a consistent diagram, in which the various specialists and departments of medicine have their proper place, properly coordinated. For example:
   a. The pelvis, examination routine, common findings and general landmarks.
   b. The kidney with special reference to undiscovered pyelitis in women.
   c. Digestive neuroses in women.
   d. The heart, its functional disturbances in women, etc., etc.

C. Post-graduate medical education. The foregoing project has been discussed with Dr. T. P. Farmer, the Committees, and a sub-committee consisting of Dr. M. C. Potter and Dr. Walter A. Calihan has been appointed to put forward plans and methods in cooperating with the Committee on Public Health and Medical Education. A course of lectures has been given to the Tioga County Medical Society, and a second course, consisting of lectures and clinics has been given to the Queens County Medical Society.

D. A questionnaire has been submitted to the Council of the Society, approved, and has been sent to the constituent County Societies. The purposes of the questionnaire are as follows:—First, to get the benefit of the experience of the local Societies for the benefit of all. Second, to ascertain the status of the subject in every part of the State, and to move toward the development of a state-wide cooperative effort. The questionnaire is herewith included so that every member of the Society may have an opportunity to aid his County Society, as his ability and inclination may urge.

QUESTIONNAIRE

1. Have you a committee on Health Examinations?
   Is it active?
   When first appointed?
   Please attach names of members, and address of chairman.
2. If there is no special committee, is this subject assigned to another committee or committees?
   If so, what?
   Please give names of chairmen.
3. Please give names of other members especially interested in the subject.
4. Has the Society
   a. Held meetings on the subject?
   b. Passed resolutions?
   c. Adopted a policy?
   d. Adopted a program?
   Please send data with this report.
5. Have you conducted a campaign for Health Examinations?
   If so, please send us data on purpose, plan, publicity, cost, methods and results.
6. Have you solicited and received the cooperation of other Organizations?
   Local?
   State?
   Federal?
   Private?
   Welfare? etc.
7. Have any of the above organizations functioned in this field independently of you?
   To what effect?
8. To what extent are industries conducting Health Examinations?
   Have you made a study of their work and its effects?
9. Have your hospitals or clinics any special Health Examination service?
   From whom may data be obtained?
10. Have you used the radio for Health Examination propaganda?
    Please send data.
    Have you any suggestions relative to its use?
11. Have you used the motion pictures for Health Examination propaganda?
    Please send data.
    Have you any suggestions relative to its use?
12. Have you used newspapers for Health Examination propaganda?
    Please send data.
    Have you any suggestions relative thereto?
13. Have you used public lectures for Health Examination propaganda?
    Please send data.
    Have you any suggestions relative to them?
14. Have you originated or procured and used any literature, pamphlets, placards, notices, etc., which you have found useful?
    Please send samples, specify sources, and make recommendations.
15. What cautions, safeguards, limitations, objections, would you urge upon the State Committee?
16. We are asked to supply speakers to address various organizations on Health Examinations. Will you furnish a list of those who are qualified and who would offer their services?
17. To what extent, if any, has the work of the State Committee come to your notice?
    Have you any recommendations with reference to its policy and program?
    How has it helped you?
    How can it help you?

E. Who conducts Health Examinations? As the Chairman studies the situation from year to year, certain of the economic features of the health examination question obtrude themselves increasingly. Certain facts appear: First, health examinations of various kinds have been done increasingly in the State for forty years, but they have been done by organizations in a more or less wholesale fashion. Health examinations by physicians in their private offices form, in comparison to this vast number, an almost insignificant proportion. This has been stated and referred to in the Committee's reports. It is important that the members of the medical profession should see the facts clearly. Therefore, the

Chairman has prepared the following estimate, which is presented as a speculative point of departure, rather than a statistical finality.

GENERAL ESTIMATE OF THE PROPORTIONATE SERVICE OF THE VARIOUS FACTORS IN CONDUCTING HEALTH EXAMINATIONS IN NEW YORK STATE

Organizations Conducting Health Examinations	*Estimated Percentage*		*Estimated Number*
1. Federal, State, City, County Examination of school children, school teachers, public employees, inmates of city, county and state institutions.		67%	2,000,000
2. Industries			
a. Qualifying examination for admission to employment.	16%		
b. Periodic check-up examination	1%	17%	500,000
3. Insurance			
a. Examinations for policies.	5%		
b. Examinations for annual check-up	2%	7%	200,000
4. Social and Philanthropic Agencies (Y.M.C.A., Y.W.C.A., lodges, labor unions)		3%	100,000
5. Doctors' Offices Health examinations done on private patients, including examinations made for citizens military training camps and pre-school health examinations of children		1½%	50,000
6. Life Extension Institute			
a. For the Public.....	15%		
b. For insurance companies..	85%	1½%	50,000
7. Health Clinics Health Examinations		.1%	3,000
8. Unclassified		2.8%	97,000

II. For the Public.

The twelve million citizens of New York State may be reached through the newspapers, motion pictures, radio, periodicals, trade journals, industries, schools, federal, state, city and county departments of various kinds, and membership organizations such as the American Legion, Y. M. C. A., Boy Scouts, Rotary, etc. An analysis of these organizations was given in our last annual report.

We can reach the public indirectly but very effectively through membership organizations which have a medium of contact from their central headquarters to the homes of their members throughout the State. Realizing this can be one of the most powerful and economical methods that could be devised, we selected the women's organizations for first operation.

A. Women's organizations. Representatives of the New York State Federation of Women's Clubs, the Congress of Parents and Teachers, and Business and Professional Women's Clubs were invited to attend the open dinner meeting of the Committee, held June 4, 1930, upon the occasion of the Convention of the Medical Society of the State of New York. This meeting was made possible through the cooperation of the Medical Society of the County of Monroe, Dr. Walter A. Calihan, Dr. William A. Sawyer, Dr. Floyd S. Winslow, and the Rochester Chamber of Commerce. It gave a strong impetus to the whole subject throughout the State. The two great women's organizations passed resolutions (printed in the State Journal, January 1, 1931,) calling upon their members to get health examinations for themselves. The New York State Federation of Women's Clubs made the health examination one of its three central projects for the year. Each of these organizations has a membership greater than our own. They have taken over our project and made it a matter personal to themselves. This is highly satisfactory. The work has only begun.

The New York State Federation reports seven special committees devoted to health affairs, such as mental hygiene, nursing, maternity, cancer, welfare of the blind, etc. The program of each of these stresses the health examination, in addition to the emphasis given by the general organization itself.

The local women's clubs throughout the State have been instructed to put on a program on health examinations during the year. They are requested to ask the State Committee on Health Examinations for a speaker. This Committee, on receipt of these requests will work through the County Medical Society in providing a speaker. It has already prepared to give its medical representative suggestions with reference to his talk, as indicated above. In addition, the State Federation of Women's Clubs will distribute to its members a pamphlet on the Health Examination, the text of which it asks our Committee to provide. This text is being carefully prepared. It will carry the gospel of the health examination exactly as we wish to state it, into every corner of the State.

In addition, the Committee has asked the State Federation of Women's Clubs to cooperate with it in the following project:

B. Radio: The Committee has been working at the radio problem for many months. Radio broadcasting has been done by local societies, notably the County of Monroe and the New York County Medical Society in cooperation with the Academy of Medicine and the New York Tuberculosis and Health Association, etc. The work of the Committee, it was realized, represented the Medical Society of the State of New York. While it should encourage and aid the local societies in their radio work, it should independently and for the State Society, establish its own radio standards, programs and outlets. Therefore, a sub-committee was appointed, consisting of Dr. Nellis B. Foster and Dr. Walter D. Ludlum. The field was searched thoroughly.

As a result, we are prepared to report that we have received the offer of an outlet, giving a thirty to fifty station hook-up every week for fifteen minutes, between ten and eleven o'clock in the morning, for the coming year. This time is best for reaching the women in the home, and coordinates with our present effort to advance the health examination for women as our major project for this year and next.

It is proposed to provide a medical speaker who will submit his talk to the Committee two months in advance to be edited and brought into harmony with the standards of the Committee. The Committee proposes to cover the field of woman's health in a substantial, practical and inspiring fashion. The second broadcast in each month will fall on the same day as the meeting of the Council. The Committee hopes to have the Officers and Chairmen of the working Committees of the Society present to the public the methods and ideals of organized medicine, with special reference to the service of the practicing physician in this oncoming field of preventive medicine. This will carry the message well and far.

C. Films: One of the most effective ways of reaching the public is by the use of the motion picture film. There are several films on this subject. They are not up to date, and the Committee feels that they can be improved. This matter is being directly investigated by a subcommittee headed by Dr. Guy H. Turrell. By the time this report is printed, it is expected that the Committee will have seen and judged all the films that may be offered. We are in receipt of a tentative request for our cooperation in the provision of not only a full-length talking film on this subject, suitable for an evening's entertainment, but also a series of short film releases to be sent out throughout the State and the Nation, at regular intervals during the next several years. This is a large project. It cannot be entered into lightly. The rewards are great. Whether or not this Committee should undertake this laborious matter is being carefully considered.

D. Press. The Committee believes that much may be done by the Medical Society of the State of New York in carrying its message to the people of the State through the public press. The Committee lacks the time, energy and funds obviously necessary to undertake this project in this field of public education. The opportunity is great, however and the field should be cultivated. Certain especially promising phases of the subject are under consideration, and are ready to be tested out in the coming year.

F. Boy Scouts of America: It is with great pleasure that the Chairman has to report that the newly organized program for Junior Scouts has made a new epoch in the field by adopting a comprehensive health examination plan which was prepared by us. This preserves the influence of the home, recognizes the service of the family physician, and trains the young boy of America to appreciate the value of the health examination.

Thus, the Chairman begs to present the foregoing as some of the work of the Committee, and in closing, begs also to express the appreciation of the Committee for the interested cooperation of the State Officers, Chairmen of Committees, and the Executives of the Society.

Respectfully submitted,

C. WARD CRAMPTON, M.D., *Chairman.*

April 15, 1931.

REPORT OF THE COMMITTEE ON PHYSICAL THERAPY

To the House of Delegates:

Gentlemen:

Your Committee on Physical Therapy continued on its work along the lines inaugurated last year and endeavored to carry out the recommendations contained in the minutes of the House of Delegates of June 2, 1930.

The principal activities of your Committee can be enumerated as follows: (1) educational, including a survey of physical therapy in hospitals of the State; (2) fostering and correlating the work of the physical therapy committees in the various county societies; (3) surveillance of the physiotherapy clause in the Medical Practice Act.

1. Your Committee transmitted to the Medical Colleges of the State the recommendation of the House of Delegates that more adequate instruction in physical therapy be given to undergraduates as well as to graduates. In order to encourage post-graduate instruction it published a list of physical therapy departments in Medical Schools and other clinics open without charge to practitioners of medicine who wish to observe the practical work in physical therapy. The attention of the County Societies was called to the post-graduate course in physical therapy offered through the Committee on Public Health and Medical Education and to the courses offered by medical institutions. Your Committee feels that further efforts are needed to stimulate more active interest of medical schools in teaching and research in physical therapy.

Manufacturers of physical therapy and *x*-ray apparatus were asked to cooperate with the Committee's effort to promote the teaching of physical therapy in undergraduate and post-graduate schools and to do away with commercial lecture courses. At a conference held with the leading

manufacturers, they readily subscribed to the principle enunciated by the Committee that instruction in diagnosis and therapy belongs solely to the province of the medical profession. The Committee wishes to thank Dr. Farmer, Chairman of the Committee on Public Health and Medical Education for his active interest in attending this conference and his continued cooperation.

Your Chairman addressed special physical therapy meetings held by the County Medical Societies of Nassau, Queens, Cayuga, Erie and Essex. Following the large attendance of the Physical Therapy Session inaugurated at last year's Annual Meeting a request was received from the Chairman of the Committee on Scientific Work for the arrangement of a similar Session at the 1931 Annual Meeting, and the Committee complied with this request.

A State-wide survey of physical therapy in hospitals was made and its result is as follows:

Number of questionnaires sent out..	250	
Number of replies received.....	173	70%

Question No. 1—
Do you possess a physical therapy department?

	Yes	*No*
Hospitals from all over the State	57%	43%
Hospitals in metropolitan zone..	65%	35%
Hospitals outside of metropolitan zone	53%	47%

Question No. 2—
Is it under the control of a qualified physician?..... 84% 16%

Question No. 3—
Do you intend organizing such a department? 34%

Question No. 4—
Can we be of assistance to you in this respect?—Number replying "Yes" 34

Question No. 5—
Would you want one of your physicians trained in order to be able to direct your physical therapy department?—Number replying "Yes"..... 11

Subsequently a pamphlet on institutional work in physical therapy was sent out to all hospitals, and emphasis was laid on the advisability of the actual direction of every physical therapy department by a specially trained physician instead of a nurse or technician.

2. During the past year nineteen (19) counties have appointed special committees on physical therapy in response to the suggestion of your Committee as compared to seventeen (17) in the previous year. The attached tabulation of the activities in the counties demonstrates that thirty-one (31) of the sixty (60) counties in the State have had some activity in physical therapy. The Chairman and members of the County Committees were regularly invited to attend the monthly meetings of the State Committee which were held for the purpose of regional contacts in New York, Albany, Syracuse and Buffalo. The Counties of Albany, Bronx, Broome, Erie, Genesee, Kings, Queens, Nassau, Onondaga and Ulster were represented at these meetings. Your Committee realizes that the most direct way to insure a better appreciation of physical therapy as an integral part of the modern practice of medicine leads through the carrying on of the work in every County Society and through the correlation of the activities of the special committees appointed in each county.

Allegany	Herkimer	Schenectady
Cattaraugus	Madison	Schuyler
Chautauqua	Monroe	Seneca
Chemung	Niagara	Steuben
Chenango	Ontario	Sullivan
Clinton	Orleans	Tioga
Cortland	Oswego	Wayne
Franklin	Rensselaer	Wyoming
Fulton	Richmond	Yates
Greene	Saratoga	

3. Your Committee welcomed the order issued on November 21st, 1930, by the Board of Regents of the University of the State of New York containing a definite regulation of the practice of registered physiotherapists. It cooperated with the Secretary of the State Board of Medical Examiners in adjusting questions relative to this practice. Your Committee is of the opinion that an amiable relationship between the medical profession and the registered physiotherapists is desirable.

Other activities. Repeated efforts were made to approach the problem of physical therapy in relation with compensation work, through cooperation with the Committee on Medical Economics. The latter Committee, however, in issuing its recent recommendations has so far not consulted with the Committee on Physical Therapy as to the physical therapy phase of the situation. Inasmuch as physical measures play a most important part in the after treatment of industrial disabilities, your Committee recommends that in carrying out the compensation agreement now pending consideration be given to competent representation of physical therapy.

The Chairman wishes to thank the members of your Committee, Floyd O. Reed of Yonkers, Philip L. Forster of Albany, Homer J. Knickerbocker of Geneva, Guy H. Turrell of Smithtown Branch, Lee A. Hadley of Syracuse and Frederic E. Elliott of Brooklyn, for their loyal cooperation and also expresses his appreciation to the Staff at the State Society Office and at the Legislative Bureau for their very kind help in the technical details of the Committee's work.

Respectfully submitted,

RICHARD KOVACS, *Chairman.*

April 15, 1931.

REPORT OF THE COMMITTEE TO STUDY THE NURSE PROBLEM

To the House of Delegates:

Gentlemen:

Your Committee appointed to study the nurse problem, reports continuous observation through personal contacts with nursing service and through association with local, county society and national committees—which are actively searching for practical solutions of the problem of furnishing adequate nursing service to the individual sick patient at a price within his means—and in furnishing adequate nursing service to the community in the discovery of disease, in protection of contacts and in active disease prevention.

During a year which has shown a continuously favorable balance in diminishing case rates and death rates from communicable disease, due largely to wider popular understanding of preventive measures—through campaigns of educative propaganda—broadcast by radio and press and by national and local agencies, the economic plight of the nurse has been worse than ever before.

A mild winter during which no widespread epidemics developed has left thousands of nurses dependent upon the charity of hospitals, or relief organizations, or upon the care of family or friends. One hospital has been feeding seventy-five nurses daily during a long period of unemployment.

During such a lean year the 2,205 schools of nursing in this country added 25,300 graduates to this already overcrowded profession, and over the border from Canada has flowed a continuous stream of well trained or poorly trained competitors, most of whom have no intention of becoming citizens of the United States—while asking the special privilege of employment at the same fee as that of our own graduates.

In spite of this great general over-supply of nurses, physicians complain of a shortage of public-health nurses able to carry on ambitious programs of disease prevention—of a shortage of especially educated surgical nurses, or of those who know anything about contagious diseases—74 out of 113 New York schools graduated 1,453 nurses who had no experience in this field. They also complain of a shortage of well schooled obstetrical nurses—only 18% of all recently graduated nurses having had any adequate training in obstetrics—revealing a serious weakness in the educational system.

More than 25,000 nurses graduating every year possessing differing educational qualifications—furnish no satisfactory protection for the patient and additional thousands of unidentified foreign graduates and practicals all demanding about the same remuneration creates a situation which demands radical reform through standardized education and strict measures of character identification.

The sick patient gets little financial relief from

the practical nurse who has had no schooling, but who has a real place in caring for mild cases in the home as working housekeeper—because she is almost as costly as the trained individual who is unwilling to adapt herself to homely although necessary household service.

The very sick patient at home needs an even more highly equipped nurse than in the hospital, where supervision and consultation with qualified heads are immediately available.

The modern tendency to hospitalize the very sick patient where he may find the best nurses as well as the best physicians generally safeguards the prognosis and lowers costs, but at the same time proper administration of floor nursing and group nursing diminishes the numerical demand upon the nurse supply.

It is quite evident that there are too many schools and too many poorly qualified nurses.

The expense of operating hospitals with graduates only, as compared with the expense of conducting a school and the employment of student nurses is now being carefully studied by the managers of several small hospitals and should be studied by all.

If the present annual number of graduates continues—no lowering fees can give them living wages—further division of their field inevitably cutting the number of working days. The private duty nurse now works only seven months out of twelve and only institutional and public health nurses have a reasonable assurance of supporting themselves by their own professional efforts. Members of your Committee believe that a promise of solution may lie along a system similar to the course of medical education. They believe that the candidate for the nursing profession, while in her high school, or special school or college where there are competent teachers should complete a prescribed course in what a nurse should know of the basic sciences of anatomy, chemistry, physiology, hygiene and biology and in the history and theory and science of nursing —and then after passing an examination—enter an approved general hospital for a residence of at least two years where she shall have a rotating apprenticeship in every service to qualify her for an R.N. degree.

Your Committee recommends a study of such a plan.

Your Committee heartily commends the visiting nurses' organizations and urges the medical profession of the State to assist their work in every possible manner.

Your Committee commends the effort of the "Committee on the Distribution of Nursing Service" under the able chairmanship of Mrs. Annie L. Hansen of Buffalo—to develop general duty and group nursing in hospitals and hourly appointment nursing service in the community either in homes, or physicians' offices, or in the hospitals, this latter service to be sold on a time basis, rather than on a visit basis. Your Committee commends the work of the "Grading Committee in Nursing Schools" for establishing the facts of nursing and nursing education in such great detail that reliable fundamental summaries, soon to be announced, may be safely used for the basic structure of a new system of nurse education.

Respectfully submitted,

NATHAN B. VAN ETTEN, *Chairman.*

April 15, 1931.

REPORT OF COMMITTEE TO FORM A PLAN TO MAKE TOXIN-ANTI-TOXIN AVAILABLE TO EVERY CHILD IN THE STATE

To the House of Delegates:

Your Committee appointed to promote the availability of Toxin-Antitoxin to every child in the State—regrets to report that the objectives of a five-year campaign started 1926 were not attained, and that one of the reasons for this failure is—the lack of enthusiastic cooperation on the part of the medical profession.

While in many sections of the state the response to the campaign was most satisfactory in attaining very nearly one hundred per cent results, in general the response of physicians was very much as it has always been to vaccination against Smallpox. The doctor seems to be afraid that he will get a patient in an unethical manner and is perfectly willing to let the Health Departments do his work for him and incidently take away his fee—and then complains about State Medicine and Government infringement upon his prerogatives.

Traditional individualism is still strong in the blood of physicians, many of whom have not wakened to the realization that if they would do their whole duty to society they must assume the leadership in community health problems which really belongs to them and for which they have been educated.

They should no longer wait to be pushed into being followers of organized lay groups which rightly enough become excited over high morbidity or mortality statistics. If State Medicine comes these doctors will take it lying down.

In spite of our disappointment in securing wholehearted cooperation the statistics shown in the following tables lifted from Dr. Godfrey's reports illuminate a splendid accomplishment in

preventive medicine and justify high hopes for the future when physicians and laymen shall have better assimilated public health education

The age group under five has been most difficult to reach as will be seen and really is the most important part of the problem for your serious consideration

Middletown led all of the cities of over 10,000 population in the percentage of immunization of children under five years of age and Putnam led the counties excluding the cities of 10,000 or over

The case rates and death rates have steadily declined since 1900 while the fatality per 100 cases has actually increased in the last 12 years

In the City of New York the brief campaign conducted by the Health Department with the active cooperation of the County Societies and Medical Practitioners has reduced the case rate and death rate to the lowest in the city's history

Here great numbers of individual practitioners have volunteered through their county societies to administer Toxin-Antitoxin free or at minimum fees and—excellent and constant publicity has been an effective stimulant of parental interest

The table on page 569, "Diphtheria, New York City Cases and Deaths," shows a sharp decline in 1930, the active year of the campaign

The campaign outside of New York City is over and it will be interesting to see the figures for the next five years

Your Committee has consulted with leaders of organized medicine throughout the State and all of them agree that publicity should be maintained by the State Departments of Health and Education and that each county society should assume as an important part of its public health program continuous stimulation of its members in taking a progressive attitude toward the elimination of a preventable disease

REPORT OF THE FIRST DISTRICT BRANCH

To the House of Delegates:
Gentlemen:

The meeting of the First District Branch was held in Hosack Hall New York Academy of Medicine, on the afternoon of October 7, 1930.

The meeting was opened with a buffet lunch which was followed by short addresses by the Officers of the Medical Society of the State of New York. This was probably the largest meeting ever held by this District, the attendance being some seven hundred.

The following officers were elected for two years: President, Charles D. Kline, Nyack; First Vice-President, C. Knight Deyo, Poughkeepsie; Second Vice-President, Samuel J. Kopetzky, New York; Secretary, Isidore J. Landsman, Bronx; Treasurer, John T. Howell, Newburgh.

The papers which were read by the following distinguished guests were both scientific and instructive.

"Symptomatology and Treatment of Diabetes," Dr. Elliott P. Joslin, Boston.

Discussion opened by Dr. Henry R. Geyelin, New York.

"Toxic Goitre," Dr Frank H. Lahey, Boston.

Discussion opened by Dr. Charles G. Heyd, New York.

"Essentials in Treatment of Fractures," Dr. John J. Moorhead, New York.

Discussion opened by Drs. James J. Sadlier, Poughkeepsie, and George A. Leitner, Piermont.

Respectfully submitted
GEORGE B. STANWIX, *President.*

April 15, 1931.

REPORT OF THE THIRD DISTRICT BRANCH

To the House of Delegates—
Gentlemen:

I have the honor to herewith present my annual report as President of the Third District Branch. The past year of the Third District Branch has been a quiet and peaceful one.

The annual meeting of the Branch was held in Albany on Friday, September 19, 1930, when the following interesting program was presented.

1. "Head Injuries," Dr. Max Peet, Professor of Surgery, University of Michigan, Ann Arbor, Mich.

2. "Surgery and Irradiation in the Treatment of Cancer," Dr. Burton J. Lee, New York City.

3. "The Poor Law and Its Relations to the Doctor," Mr. Clarence E. Ford, Assistant Commissioner, State Welfare Department.

The following officers were elected for two years:

President: Herbert L. Odell, Sharon Springs; First Vice-President, Clark G. Rossman, Hudson; Second Vice-President, Luther C. Payne, Liberty; Secretary, William M. Rapp, Catskill; Treasurer, Ernest E. Billings, Kingston.

The attendance was in the neighborhood of one hundred.

For several years now the meetings have been held in the large cities of the District and the attendance has not been what it should be and the retiring President would respectfully suggest that hereafter, for a few years at least, the meetings be held in the smaller cities or towns of the District.

On the 12th of December your President and the Executive Officer of the State Society attended a complimentary dinner of the Delaware County Medical Society in honor of Dr. Rayvesky and Dr. Payne. About a hundred physicians with their wives were present. Dr. Rayvesky although ill made a heroic effort to attend. A few days after the dinner he passed on to that place where patients do not telephone in the middle of the night and all is peace and quiet.

The Rensselaer County Medical Society celebrated the one hundred and twenty-fifth anniversary of their organization in December. A dinner was held at the Hendrick Hudson in Troy which was largely attended.

Mainly through the efforts of the Greene County Medical Society a hospital is to be established in Catskill which will serve as a county hospital and fill a long felt want.

In Ulster County a new tuberculosis hospital is to be founded, in the organization of which the members of the County Society took a leading part.

The meetings of the Columbia County Medical Society have been well attended.

In Schoharie County, the home of the new President, the meetings have been well attended and a new interest aroused in the economical side of medicine.

In Albany County the monthly meetings have been well attended and interesting programs presented. The Society is planning to celebrate the one hundred and twenty-fifth anniversary of their organization in the fall. Just what form this celebration will take has not as yet been decided.

In conclusion your retiring President wishes to thank the officers and members of the Branch for their unfailing loyalty and support which they have given him during the four years of his administration.

Respectfully submitted,

EDGAR A. VANDER VEER,
President.

April 15, 1931.

REPORT OF THE FOURTH DISTRICT BRANCH

To the House of Delegates—
Gentlemen:

The outstanding feature of this year's work is unquestionably a report delivered to the entire Fourth District Branch at its fall meeting in Saranac Lake by Mr. William M. Bronk, Welfare Commissioner of Washington County. The Commissioner pointed out the organization of the work done in Washington County with his views, which for a layman are rather unique. It is his belief that doctors are as much entitled to their pay for services as is the grocer or coalman for the materials delivered to indigent patients. The meeting went far beyond the supper hour with discussion which was participated in by practically every member of the Society. We are seeing some fruits of this report in other portions of the State where county medical societies are getting together with their welfare commissioners as was done in Washington County. Such constructive speeches are always good for medical men to hear.

Warren County through its President, Dr. Floyd Palmer and the Chairman of the Public Relation Committee has been very active, taking particular interest in public health work. Through an arrangement with the Board of Supervisors and Chairman of the Public Health Committee, Mr. Nelson A. Moss, a committee from the County Medical Society sits in eacl

month with a committee from the Board of Supervisors and listens to the reports and discussion concerning the work. This has been an admirable thing resulting in benefits both to the Medical Society and the Board of Supervisors. In addition to this they have conducted some extension work. Dr. Harlow Brooks has given a wonderful talk on "Angina Pectoris," which was freely discussed. Also a report and speech with relation to county health departments was given by Dr. Munson of Granville. The County Society has been active in supporting good public health measures at hearings in Albany and opposing bad measures.

Essex County with Dr. Harold J. Harris has been active in legislative matters. Dr. Kovacs is scheduled to address a forthcoming meeting.

Schenectady County Medical Society has had a very profitable year. They devoted much of their time to scientific medicine, having had speakers from various parts of this country and Canada.

The County Medical Society of Montgomery has had a year of very excellent relations with their Board of Supervisors with whom they have cooperated very extensively. This has resulted in finishing an up-to-date Sanitarium for Tuberculosis and also in extending the county laboratory services with branch laboratories and technicians at the Sanitarium and at Canajoharie. The County Society has also gone on record in favor of a county health department.

The Saratoga County Medical Society during the year has established the practice of four rather than two meetings and they have established weekly laboratory clinics which are held at the Saratoga Hospital. The Committee on Legislature and Public Health has been particularly active.

The Clinton County Medical Society have had the following activities:

(1) Post-graduate course in Neurology under the auspices of the Committee on Public Health and Medical Education.

(2) Completion of the Maternity Surveys of 1929. This covers the births handled by physicians and the answering of questionnaires concerning the phases of the cases.

(3) Appointment of committee to study and report on matter of charges to be made under the new Public Welfare Law.

This latter is an outgrowth of the discussion at the Fourth District Branch meeting.

During the year the Fulton County Medical Society held their regular meetings, which were attended by various outside speakers, Dr. L. Whittington Gorham, Albany, "Infectious Mononecleosis," Dr. Arthur Crede, New York, "Surgery of the Knee Joint," Dr. William Ordway, Mt. McGregor, "Undulant Fever," Dr. William Ross, Brentwood and Dr. Joseph Lawrence, Albany, "County Health Programs."

Respectfully submitted,

WILLIAM L. MUNSON, *President.*

April 15, 1931.

REPORT OF THE FIFTH DISTRICT BRANCH

To the House of Delegates—
Gentlemen:

As President of the Fifth District Branch of the Medical Society of the State of New York, I respectfully report as follows:

The Executive Committee of the Fifth District Branch, the Presidents of the component County Societies and Dr. Joseph S. Lawrence, Executive Officer of the State Society, attended a luncheon at the Hotel Utica, Utica, on Thursday, June 12th, for the purpose of discussing plans for the Annual Meeting. There was a full attendance and Dr. Lawrence gave an instructive talk touching on the policies and plans of the State Society.

An invitation received from Dr. V. M. Parkinson, President of the Herkimer County Medical Society, to hold the Annual Meeting at Little Falls was accepted. The Annual Meeting was held at the Masonic Temple, Little Falls, September 30, 1930. A chicken dinner was served at the Hotel Snyder at 1:00 P.M.

The District was honored by having as guests Dr. William H. Ross, President of the State Society, who always has a message; Dr. Daniel S. Dougherty, Secretary; Dr. John A. Card, Speaker; Dr. G. M. Fisher, Ex-President, and Dr. Joseph S. Lawrence, Executive Officer. The following scientific program was given:

Meeting called to order by the President, Dr. Augustus B. Santry, Little Falls.

Address of Welcome by the Mayor, John M. Tanzer, D.D.S., Little Falls.

"Some of the Newer Anesthetics," Dr. George S. Eveleth, Little Falls.

"Goitre," Dr. Frank H. Lahey, Boston.

"Medical Shock," Dr. Dana W. Atchley, New York.

Luncheon was served at 1:00 P.M. in the Hotel Snyder, the Medical Society of the County of Herkimer acting as host..

AFTERNOON SESSION, 2:00 P.M.

"Treatment of Varicose Veins," Dr. John Sutton, Jr., New York.

"The New Public Welfare Law," Hon. Richard W. Wallace, New York State, Department of

Social Welfare, Albany. R. W. Wallace was represented by Mr. Ford of the Department of Social Welfare and his explanation of the New Welfare Law was very instructive.

County Societies all report that they are going forward with the policies of the State Society and all its activities, but report a small attendance at their Meetings.

A great many physicians are suspicious and fearful of all Health Department activities and don't seem to understand the line of progress of preventive medicine. They are afraid of "State Medicine," or "Something." We lack organization. Every physician should attend all the meetings of his County and District Branch. Get together. Organize. Organize and protect sick and suffering humanity and our noble profession.

Respectfully submitted,

AUGUSTUS B. SANTRY, *President.*

April 15, 1931.

REPORT OF THE SIXTH DISTRICT BRANCH

To the House of Delegates—

Gentlemen:

The Executive Committee of the Sixth District Branch, the Presidents and Secretaries of the County Societies of this Branch, met at the Country Club at Owego on June 18, 1930. Dr. Joseph S. Lawrence, Executive Officer of the State Society, was with us. There were ten present. Luncheon was served at the Club House and a program was arranged and the place and date of the Annual Meeting fixed.

At the Annual Meeting held in Cooperstown, September 23, 1930, we were honored by having with us, Dr. William H. Ross, President of the State Society, Dr. Daniel S. Dougherty, Secretary, of the State Society, Dr. John A. Card, Speaker of the House of Delegates, Dr. Joseph S. Lawrence, Executive Officer, and about two hundred members.

Respectfully submitted,

GEORGE M. CADY, *President.*

April 15, 1931.

REPORT OF THE SEVENTH DISTRICT BRANCH

To the House of Delegates—

Gentlemen:

As President of the Seventh District Branch, I wish to make the following report.

The Executive Committee of the Seventh District Branch met in the Hotel Seneca in Rochester and discussed plans for the meeting in September.

This was an exceptionally interesting meeting as the class of papers to be given was discussed with a great deal of enthusiasm.

It was decided to hold the annual meeting at Keuka College, Keuka Park, on September 25, 1930. At this meeting although a very interesting program was offered the attendance was not as good as we anticipated, only about 100 physicians being present at the meeting.

Perhaps Monroe County has taken the lead in progress of any of the counties in the Seventh District Branch in any of their activities.

The Society has been broadcasting interesting talks for the last year and a half. These talks are under the physicians of the Public Health Committee of that county of which Dr. Sawyer is Chairman.

The Committee select the speakers and censor the papers before they are broadcast.

The County Medical Societies are standing the expense of the broadcasting which is given each Sunday night.

I have visited several of the County Medical Societies during the year and most of them are doing some public health work.

I attended the meeting of the Council in Rochester last May and also the meeting in December in New York City.

These reports are being submitted to you by their respective heads.

Respectfully submitted,

E. CARLTON FOSTER, *President.*

April 15, 1931.

REPORT OF THE EIGHTH DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The Executive Committee of the Eighth District Branch met at the Hotel Statler, Buffalo, in August, 1930. At this time we decided to have the twenty-fifth annual meeting at the J. N. Adam Memorial Hospital, Perrysburg, on October 2nd. The idea was a very happy one for we were able to make a tour of an extremely interesting hospital and Dr. LoGrasso was a most generous host.

After a tour of inspection Dr. LoGrasso read a paper on "The Value of Light in the Treatment of Tuberculosis." His paper was discussed by Dr. Brian O'Brien of Buffalo. The members of the Society were guests of the hospital at an elaborate luncheon. In the afternoon Dr. W. H. Ross, President of the Medical Society of the State of New York, talked briefly on medical leadership in health work. Dr. John Card, Speaker of the House of Delegates, discussed some phases of liability insurance.

The following papers were read:

"Epilepsies—Etiology and Diagnosis," William T. Shanahan, M.D., Sonyea; discussion, Edward A. Sharp, M.D., Buffalo.

"The Salient Features of Surgical Diagnosis in Conditions of the Abdomen," Charles G. Heyd, M.D., New York City; discussion, George W. Cottis, M.D., Jamestown, and Marshall Clinton, M.D., Buffalo.

The meeting was altogether one of the most successful and interesting ever held by the Eighth District Branch. More than three hundred and fifty were present and all had a very good time both intellectually and socially.

Respectfully submitted,

W. Ross Thomson, *President.*

REFERENCE COMMITTEES

Dr. John A. Card, Speaker of the House of Delegates, has appointed the committees to whom the reports of the officers and committees are referred for consideration and suggestion of action. The early publication of both the reports and the personnel of the reference committees will afford the members of the State Society the opportunity to express their opinions, and their representatives in the House of Delegates to reflect the attitude of their constituents.

THE REPORT OF THE PRESIDENT

Luther F. .. , County
Floyd S. . Monroe
Augustus nsselaer
Norman J. ... . . . Jefferson
Joseph B. Hulett.....Middletown, Orange

THE REPORTS OF THE SECRETARY, THE COUNCIL, COUNCILLORS, AND THE BOARD OF CENSORS

William A. Krieger, *Chairman*,

THE ANNUAL REPORTS

This Journal contains 112 pages—forty per cent more than the normal issue of 80 pages. The increase is due principally to the annual reports, which are of unusual length and interest because of the increasing number and importance of the activities of the Medical Society of the State of New York.

The reports are addressed to the House of Delegates; but specifically, each goes to a reference committee whose members recommend the action for the House to take. Let each member of the State Society imagine himself to be on a reference committee as he reads the reports and judges their practical application.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 21

As the year's contacts with County Medical Societies and their activities draw to a close, one almost subconsciously begins to think of the changes in medical opinion regarding relationships to other health interests in the State, the attitude toward medical problems and the growing tendency to assume somewhat more of a constructive effort to meet conditions that are steadily pressing for solution. Unfortunately we still have to destructively oppose many legislative proposals, some of them year after year, and they have to be settled in the same way by legislative vote.

There are problems before the profession year after year which ought to be more actively opposed by the Department of Education. This Department sets up standards for medical licensure. Several thousands have met these standards and have been licensed to practice medicine. It would now seem that an obligation rests upon the Department of Education to defend its required standards of professional education and not leave them to be defended so largely by the profession of medicine.

Medicine has for about three years increasingly discussed its problems of relationships, the public unrest, and the real influence of social conditions on the problem of the distribution of health and sickness service. There is a tendency to develop a constructive medical program. We have not yet gone very far but there is a new interest and a growing willingness to think these things through.

That scientific medicine has advanced farther than its availability has advanced is beginning to be understood. Many physicians believe that medicine would profit economically if sound procedures could be devised so as to protect individuals from the hazard of sickness by distributing the costs. Objectionable features permitted by some countries must be guarded against. This could be thought out by medicine if aided by expert opinion, such as actuarial service. It would make medicine more available to certain classes and would provide for compensation of the physician for these same classes to which he now contributes his services.

If there is no challenge there can be no progress. This principle is an incentive to work out constructively professional problems. Just that which has been brought out so many times in the last year or two in current literature may be having a stimulating effect on the profession. These things may be arousing medicine to assume more definitely than it has done, leadership in public medical affairs.

The profession of medicine ought to determine definitely its public policy. People have become more health conscious. Disease prevention is the hope of the future and the public is ready to be taken into confidence. Notwithstanding expressed opinion occasionally that public health activities should not be advanced, there are many evidences over the State of great advance in places where the public and medicine are cooperating.

In the President's report this year an effort has been made to discuss features that have come under his observation and to draw some obvious lessons from them. Far greater, however, than the obvious lessons are the intangible influence of opinion, mental attitudes, and cooperation that will continue to flow from these efforts. Generally speaking there is an indication over the State of a spirit of cooperation with public interest. There is greater civic interest on the part of the public. While public health has always been the concern of nations there has never been a time when there was more dependence ready to be placed upon the profession of medicine or when greater expectation existed that medicine should lead in all health activities.

The medical profession is absolutely indispensable in all programs of health and sickness service. Most of the public realize this. A comparatively few do not realize it. Among these are some intelligent people. An illustration occurred recently. A Senator speaking for a cult bill said, "For one hundred dollars I had a kink rubbed out of my shoulder that I might have paid a physician five hundred dollars for without result." This intelligent gentleman persuaded himself that he is able to get better medical service from an untrained individual than he could get from well trained physicians.

The profession of medicine surely has the capacity to change by a plan of ethical publicity. Occasionally one hears the representatives of groups of people say that the medical profession is not interested in them except when an individual is sick. If public benefit is to come from existing medical science there is an obligation resting upon us, as a profession. Organized medicine should constructively present sound policies regarding at least the major problems which are generally accepted as commanding public interest today.

Primarily, "Medicine is an art, not a trade; a calling, not a business."

In all conferences and in all bodies deliberating upon the medical phase of public welfare, physicians should have representation enough and be active enough to present plans of sound medical relationships. Medicine would hardly dictate the whole relationship any more than law or government, through legislation, would undertake to enact any regulation at variance with public opinion. Medicine must formulate its policy and present its plan constructively if the position of medicine is to grow into the indispensable position

in all public medical affairs that every physician would like to see it occupy.

We owe the public our assistance in establishing a standard of what is adequate service and as to what the public should expect medicine to provide. The observations of the year show that the profession of several counties of the State is helping the public to inform itself on medical problems and medical services. Wherever this has occurred, it has profited both the public and the profession.

During the year the President has read rather extensively the history of medicine in other countries in the writings of Rappleye and others. The history of medical organization in Denmark and the remarkable present day results are interesting. Their one hundred thirty year old method of controlling venereal diseases, the maternity mortality rate in Denmark, the degree of its hospitalization, the general prosperity of all classes, the general use of sickness insurance, and the twenty to thirty thousand kroners yearly income of physicians (five to eight thousand dollars), are at least interesting reading. Each of the twenty-three counties has from one to three hospitals where the major part of medical and surgical work is done. Every health officer in Denmark holds office for life. They are pensionable. They are appointed by the government and subject to central regulation. Every health officer is a State officer and among his duties are treating the poor who are not insured and treatment for the prevention of disease.

This may be thinking too far ahead. Physicians in the present, however, will lose nothing by planning for the future.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Centennial of Orange County Society:—This Journal of May, 1906, contains the following note:—

"The centennial anniversary of the founding of this society will be celebrated in July. An appropriate feature of the commemoration of this event will be historic reviews of the lives of the notable physicians who have labored in this community. Dr. John H. Thompson will present the history of Dr. Benjamin Tusten, who introduced vaccination into Orange County, served as soldier in the Revolution, and who as colonel and surgeon fell at the battle of the Minisink. This memorable battle, or massacre, for such it proved, witnessed an act of splendid heroism in Colonel Tusten. The historian says that, while the battle was raging, and before the alternative of massacre or flight had culminated in the conflict, Dr. Tusten had gathered the wounded in a sheltered place behind a cliff of rocks when the privileged retreat commenced. There were seventeen disabled men under his care at the moment, to whom he was ministering; and while thus engaged they were all attacked by the savages, and with relentless cruelty every one perished under the tomahawk and scalping knife. Though the opportunity with the others who had fled was available on the part of Dr. Tusten, nevertheless he voluntarily remained at the post of service, performing with self-sacrificing fidelity the humane offices of the ever dutiful and faithful physician. He thus died at the early age of thirty-six, protecting the wounded whom the fortunes of war had placed within his care."

MEDICAL PROGRESS

The Endocrine Function of the Salivary Glands.—There are a number of definite facts, say M. and F. Cahane, that demonstrate beyond a doubt that the salivary glands possess an internal secretion. The first observations to suggest this hypothesis were in the field of the pathology of the parotid gland. Medical science has long been familiar with the frequency with which orchitis occurs with mumps. After an exhaustive research it is still impossible to conclude whether there is a direct relation between the parotid gland and testicle; it is only known that in these cases orchitis makes its appearance during or after the parotid congestion. On the other hand it is interesting to emphasize that we may see pancreatitis following mumps. In view of the well known fact that troubles of internal secretion of the pancreas form part of the clinical picture of pancreatitis, the authors call attention to a case they have recently observed in which a young man had hypertrophy of the parotid glands associated with diabetes mellitus. The hypertrophy had followed mumps, and 5 years later diabetes also appeared. This case suggests the desirability of studying the carbohydrate metabolism during mumps. The authors have shown experimentally in six dogs that 7 to 12 days after extirpation of the submaxillary glands there was an increase of blood sugar. During several months that these animals were under observation there were no signs of cachexia. Their own observations led the authors to conclude that the parotid gland behaves as an antagonist toward the pancreas, whereas the submaxillary gland is synergistic with the latter. Histologically the resemblance of the salivary glands to the pancreas has long been known, so that the name abdominal salivary gland has even been conferred upon the latter. This leads naturally to the supposition that the salivary glands have an endocrine function that accords with their normal histologic structure. The only one of these glands of which the product of secretion has been isolated is the submaxillary, the chemical character of which resembles that of insulin. Extirpation of the submaxillary glands causes hypoglycemia and increase of the glycogen of the liver. Specific troubles caused by their extirpation may disappear if grafts are carried out or injections of their extracts made. Although there are still obscure points in this connection which demand more research, the facts already acquired entitle the salivary glands to a place among the endocrine glands, and accord them an important rôle in the organism.—*Revue française d'endocrinologie,* October, 1930.

Salicylic Acid Fruit in the Prevention and Treatment of Rheumatism in Children.—Starting with the supposition that rheumatism in children is secondary to a metabolic or vitamin derangement, J. Epstein made a clinical, dietetic, and therapeutic study of 33 normal children and 98 rheumatic children, extending over five years. A survey of the diet taken by the rheumatic children showed in a general way that the children received an abundance of food of fair variety and quality, but with a decided deficiency of fresh vegetables and fruits. Salicylic, benzoic, citric, and tartaric acids are antirheumatic. They are found in various proportions in a free state, or in a form of a precursor, in strawberries, huckleberries, raspberries, plums, cherries, lemons, grapefruit, and melons. The organic acids in these fruits inhibit intestinal putrefaction, reduce toxemia and the indicanuria so frequently found in rheumatic disorders (in over one-half of the 98 cases). The alkaline ash, which is formed in the process of metabolism of the organic acid salts, aids in neutralizing the acid products of the tissues and of bacteria. It also reduces the acidity of the urine, saliva, and sweat, so common in rheumatism. None of 20 normal children who were given an abundance of salicylic acid fruit developed any signs or symptoms of rheumatism. In the 98 rheumatic children foci of infection were removed and every possible means was taken to improve their general health. Of this group 83 children received salicylated fruits with uniformly favorable results, while those who did not take these fruits did not progress so satisfactorily. Failure in the treatment of rheumatism in children is mostly due to the fact that they are treated sporadically with salicylates in large doses, which injure the tissues of the body and diminish resistance, while the salicylated fruits can be given over a long period of time, with uniformly beneficial results. Beginning with the second year of life juices of these fruits should be added to the diet to prevent rheumatism. The general plan for the management of rheumatic children includes conservation of body strength, removal of infected foci, a dry, warm climate, a nutritious diet, and salicylated fruits. The children in the cardiac group who, in addition to the usual hygienic care, received salicylated fruits showed better therapeutic results than the controls.—*Archives of Pediatrics,* February, 1931, xlviii, 2.

Protective Therapy of the Air Passages.—Discussing the very special laws governing the

air passages by virtue of their ciliary epithelium, Ludwig Bauer points out that it is only possible for the deeper of these passages to perform their function through the span of a lifetime if there is proper coordination between the various parts of the respiratory tract, so that all its defensive mechanisms can interact with mutual precision. Every cell of this epithelium is provided with a vibratory cilium, sensitive to every change of external condition, such as lack of moisture or warmth. Even a slight lowering of the temperature causes this ciliary motion to cease. In addition the large number of mucous glands pour a constant stream of secretion over the surface of the mucous membranes, and a constant stream of leucocytes is always being forced through to the surface epithelium from the underlying tissues. The extreme sensitivity of these membranes points the way to a logical and effective therapy whenever their normal relations are disturbed. Sparing them from irritation is the first law for every form of affection of the air passages. The good results of the silence treatment have already pointed in this direction, showing to what an extent the withholding of irritation enables the diseased mucosa to recover through its own powers. In this class of treatment belongs the introduction of a properly adapted breathing air. The inhalation of salty air in a room impregnated with brine will possess all the prerequisites for avoiding every irritation of the mucous membranes. Not only are the proper warmth and moisture secured, but because of the brine there is provided an isotonia of the particles of moisture that enter the breathing passages. Should there by chance be a hypertonia present, it is advantageous rather than otherwise, as it merely increases the activity of the mucous glands. But for tender, sensitive cells, only the physiologic solution presents the medium which will preserve without injury their protoplasmic characteristics. Hence in all affections of the air passages, the best results are produced by the breathing as quietly as possible of salt air, combined with silence therapy and short, humming expirations. Only in this way will the mucous membrane be in a position to mobilize a maximum of resistance and to remanufacture the qualities indispensable for permanent normal functioning.—*Münchener medizinische Wochenschrift,* February 6, 1931.

Treatment of Spasmodic Croup Based upon Clinical Findings in the Colon.—Lawrence P. Crawford believes that spasmodic croup is a result of absorption of colonic toxins from the small intestine. He has found acetone in the urine of 100 per cent of patients with spasmodic croup and there have been areas of dullness and tympany on percussion over the colon in all patients with this affection. If a child is permitted to go to sleep with impacted feces and pocketed gas in the colon, it seems reasonable that relaxation of the muscles produced by sleep would allow either exit of the gas via the rectum or would force colonic toxins through the ileocecal valve into the small intestine. This causes spasm of the larynx and awakens the child. In a few cases of spasmodic croup in adults the author has found that the urine showed a continuous acetone reaction, and *x*-ray examination has revealed atonic and hypertonic areas of the colon musculature, and an incompetent ileocecal valve. Treatment directed to the colon musculature resulted in restoration of a uniform tone in the colon, acetonuria disappeared, and the patient had no further attacks of spasmodic croup. In over 100 cases of spasmodic croup treatment of the colonic condition has been uniformly successful. Three small soapy water enemas will usually remove the impacted feces from the colon. More than one-half pint should not be given to a child or one pint to an adult at one time. The elevation of the fountain syringe should not exceed twelve inches. As soon as the first enema is expelled, the second is given, and when this is evacuated the third is administered. Other medication is unnecessary. Toxic manifestations, other than spasmodic croup, which are probably frequently due to the absorption of colonic toxins from the small intestine are nosebleed, uterine bleeding, eczema, bronchial asthma, and an arthritis that is not due to ordinary focal infection. It is therefore as important to know the status quo of the ileocecal valve as it is to know the condition of the tonsils, teeth, or sinuses. It is as important to know how to diagnose and treat an incompetent ileocecal valve as it is to know how to diagnose and treat an infected sinus or its complications.—*New England Journal of Medicine,* February 26, 1931, cciv, 9.

Arteriovenous Anastomosis in Raynaud's Disease.—On the basis of a case in which he operated Trincas Mario discusses the value of arteriovenous anastomosis in Raynaud's disease. The procedure consists in utilizing the veins to send the blood to the disease tissues which are suffering with gangrene from under-nourishment, and in letting it flow back through the arteries. Despite the statements of certain authors that the valves of the veins offer an insurmountable obstacle to the centrifugal current, clinical results in many cases have shown immediate benefit. In fact, in the case under discussion, where the anastomosis was femoro-femoral, the first phenomenon observed was the mitigation of the pain for hours at a time, such as had not occurred in many years. The cyanosis disappeared from the foot except the great toe, the temperature of the foot increased, but without surpassing that

of the other thigh (previously amputated at lower third) However, the improvement was ephemeral, all the symptoms returning after 25-30 days with even greater gravity When arterial blood is made to flow in a vein if it does not encounter obstacles in the form of the valves it reaches the last branchings of the veins with ease But since the pressure of the arterial blood is gradually reduced as it approaches the capillaries, and especially because the pressure in the arteries is positive, the blood stream is arrested At the level of the capillaries there is established a confluence of two hydraulic streams animated by the same propulsive force, with the difference that the normal one is directly sustained by the systolic pulse, while the inverted one is not aided at all in its reflux course by the diastolic aspiration of the heart, thus it becomes blocked by the normal arterial current The result is a stasis of the blood, manifested by the usual characteristics of hyperemia which is easily mistaken for improvement But this state of affairs cannot last long, for the increase of intravenous pressure will oblige the mass to become distributed by centripetal tracks, thus favoring the formation of collateral routes The collateral stream will then annul the passive hyperemia and will gradually reestablish the preoperative conditions In this case the disease resumed its inexorable course after a brief respite, and as in the other limb amputation was necessary —*Riforma medica* February 9, 1931

Sympathectomy for Megacolon —D E Robertson reports three cases of megacolon, or Hirschsprung's disease, successfully treated by interference with the lumbar sympathetic trunk, and in a footnote he states that since writing this paper he has had three additional cases of megacolon in which sympathectomy resulted in a cure He recalls that Royle, who devised an operation for the relief of spasticity of the lower extremities in cases of upper neurone lesions observed in his first case that the patient was cured of constipation, and subsequently he reported 13 additional cases thus cured He believes that Gaskell's explanation of the innervation of the bowel is correct, viz , that the large bowel is supplied by both the sympathetic nervous system and the parasympathetic pelvic nerve The pelvic nerve is concerned with the movements of the bowel, while the sympathetic nerves are inhibitors of bowel action and also control the sphincters of the bowel In the cases here reported Robertson employed the approach to the lumbar sympathetic advocated by Royle An incision is made which extends from the twelfth rib down to the posterior superior spine and around the crest of the ilium to near the anterior superior spine The trigonum lumbale is located and pierced Through this opening the finger is able to identify the lateral edge of the erector spinae muscles, and the incision is carried upward through the fascia and across the lower fibers of the latissimus dorsi In the lower part of the wound the attachment of the external oblique is divided from the ilium The fingers then separate the fascial planes, care being taken to keep close to the peritoneum The fingers pass over the psoas muscle to feel the bodies of the lumbar vertebrae, on which may be felt a small cord, covered with fascia Through an opening in this fascia the lumbar sympathetic is raised on hooks and freed from fascia to the level of the first lumbar vertebra and as low as the fourth lumbar enlargement Royle divided the white rami communicantes, and the branches which ran mesially from the second, third, and fourth enlargement In two of his cases Robertson removed the entire lumbar cord from the level of the second enlargement Associated with the relief of the bowel condition in these cases, there was a decided improvement in the temperature of the leg denoting an increased blood supply —*Canadian Medical Association Journal*, March, 1931, xxiv, 3

The Processes in the Circulation During Shock —According to G Ganter and A Schutzenmayer, the chief finding in the circulation in shock in the human being is the fall of blood pressure If this fall were due, as some authors teach, to a contracting mechanism in the lungs or liver, the administration of relaxing drugs, such as nitrites, would tend to overcome or at least improve the threatening changes of the circulation But this is not the case, as the authors were able to show by animal experimentation If, however, the drop of blood pressure in shock is the result, as they assume, of a general peripheral loss of tonus of the vessels, then a remedy which produces a tonus reaction opposite to the effect of a shock poison would be able to compensate the drop Such a drug exists in adrenalin or ephedrin, which has the effect of increasing the tonus of all arteries of the systemic circulation which are innervated by the sympathetic system As a matter of fact this is precisely what occurs in animal experiments; the marked drop in blood pressure in shock is compensated by ephedrin injection Conversely, the contraction of vessels, that is, the increase of blood pressure by means of adrenalin, is suppressed by corresponding amounts of histamine The authors were led to conclude that the lowering of blood pressure in anaphylactic shock from histamine and peptone is due neither to a pulmonary nor to an hepatic contraction, but is the result of a general dilatation of the arteries of the greater circulation Since dilatation of the body arteries occurs in just the same way after

exclusion of the vegetative system by gynergen and atropine, the conclusion seems warranted that the shock poisons act directly upon the vessel musculature without intermediary action of the nervous system. After these experiments, the theory of a pulmonary or hepatic contraction seems no longer tenable. In view of the demonstration that there is a general dilatation of the arteries of the greater circulation as a fundamental effect of shock poisons, and of the fact that this dilatation is overcome and the blood pressure raised by substances acting like adrenalin (ephetonin, ephedrin), the treatment of shock with ephedrin and similar drugs should be the method of choice.—*Klinische Wochenscrift,* March 14, 1931.

The Interpretation of Pain in Infancy.—Wilfred Sheldon, writing in the *British Medical Journal,* March 28, 1931, i, 3664, calls attention to the help that may be gained in the interpretation of pain in infancy by noting the character of the cry, whether it is intermittent or continuous, piteous, wailing, or a short, sharp scream. Whether it occurs at a particular time of the day or night and its relation to the time of feeding should be noted. The baby's posture during bouts of pain should be observed, and the clinical examination may reveal areas of tenderness, indicating the location of the pain. The commonest cause of gastrointestinal pain is some error in diet. If the pain arises in the stomach, it will usually be manifested within a few minutes after feeding; if the cause is further down in the intestinal tract, pain is likely to occur from half an hour to an hour after taking food. If the fault is unchecked, chronic indigestion will follow and pain will become continuous. Excessive peristalsis leads to colicky contractions with intermittent pain. The baby cries at intervals of a few minutes, draws his knees up to the abdomen, presses his elbows to his sides and maintains this attitude for two or three minutes. When a baby sucks for a few minutes and then cries and refuses to continue sucking, the breast may be empty, the hole in the rubber nipple may be too small, or there may be a painful condition in the infant's mouth, such as catarrhal stomatitis, thrush, or small shallow ulcers. Screaming while having a bowel movement is usually the result of constipation. Occasionally, especially in females, there may be anal spasm, which may be detected by digital examination. Another cause of painful defecation is anal fissure. In a previously healthy baby, the sudden onset of screaming and intestinal colic, with attacks recurring every few minutes, is suggestive of intussusception. Volvulus, strangulation by peritoneal bands and appendicitis are marked by sudden vomiting, constipation, abdominal distention, and collapse. Screaming with irritability, fever, and often mild diarrhea should lead to a careful examination of the ears, a procedure too frequently omitted. Attacks of sharp screaming may occur in the first stages of basic meningitis or of tuberculosis. Pain during micturition may be due to highly acid urine coming in contact with excoriated buttocks, to the passage of oxylate crystals, or in boys to an ulcer at the urinary meatus. Severe attacks of pain may occur in pyelitis. Pain in the limbs should suggest syphilitic epiphysitis, scurvy, osteomyelitis, or acute poliomyelitis.

Autohemotherapy in Mental Diseases.—Eustachio Zara says that the frequency with which states of mental confusion are accompanied by morbid conditions of the intestinal tract induced him to make a trial of autohemotherapy in these cases. While it cannot be said that all the syndromes of mental confusion are caused by intestinal changes, or by other known infections, it is certain that the so-called idiopathic mental confusion is becoming more rare as improved clinical and biological methods of examination reveal more and more the presence of a toxinfectious state in such patients. Zara accordingly subjected 10 cases of acute psychosis to autohemotherapy, nine of these being cases of mental confusion and one a case of schizophrenia. In four of the nine cases complete cure resulted, and there was distinct improvement in the other five. It is possible that some of these might have been wholly cured if the insistence of relatives had not caused them to leave the hospital prematurely. The case of schizophrenia was also improved in the sense that symptoms of grave agitation disappeared temporarily, so that the injections may at least be regarded as a useful sedative treatment in such conditions. The technique is simplicity itself, consisting of the reinjection into the gluteal region of whole blood taken from the elbow with a common syringe. In every case an initial injection of 2 c.c. was made to test the tolerance; this was then slowly increased to 15 cc. with careful observation of the general condition and especially that of the kidneys. No injurious effects were ever observed in these organs, nor was there any appreciable or constant modification of the differential blood count, or of the blood pressure, nor any other symptom indicative of shock or intolerance. While therapeutic effects did not appear as promptly as usually occurs in organic diseases, there was first observed an improvement in the general condition and in the state of agitation; then gradually the state of confusion wore off, complete psychic reintegration returning in some cases. The fact that autohemotherapy has been found particularly efficacious in infectious diseases offers indirect confirmation of the infectious origin of acute confusional syndromes. The innocuousness and simplicity of technique of autohemotherapy render it a useful and rational therapeutic aid in these conditions.—*Riforma medica,* March 2, 1931.

LEGAL

PRIVILEGE AGAINST SELF-INCRIMINATION—WAIVER

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

One of the fundamental principles of our legal system is that a man may not be compelled to give evidence against himself in a criminal prosecution. The Bill of Rights in the Constitution of this State (Article I, Section 6) provides in part as follows: "No person shall * * * be compelled in any criminal case to be a witness against himself." This provision is the counterpart of a like provision found in the Fifth Amendment to the United States Constitution. The privilege thus secured is purely personal to the individual, and may be waived expressly or by operation of law.

In considering this topic, it is necessary to consider the legal situation, first, where the individual is not a defendant in a criminal case but is simply a witness and, secondly, as it concerns the defendant in a criminal case.

Suppose, for example, a man who is not himself a defendant but is called as a witness in the case, answers certain questions and then refuses to answer certain others on the ground that they may tend to incriminate him. The question arises as to whether by answering certain questions he has waived the constitutional privilege as to all other questions. A learned Judge once stated the rule to be as follows:

"Where he has not actually admitted criminating facts, the witness may unquestionably stop short at any point and determine that he will go no further in that direction. * * * But the rule which allows a witness to refuse answering questions not pointing directly to guilt, rests solely on the doctrine that, as in most cases the crimination would be made out by a series of circumstances, any one of them may have such a tendency to aid in reaching the result, that an answer concerning it may supply means of conviction, by aiding the other proofs which it indicates or supplements, on behalf of the prosecution. The right to decline answering as to these minor facts is merely accessory to the right to decline answering to the entire criminating charge, and can be of no manner of use when that is once admitted, and must be regarded as waived when the objection to answering to the complete offense is waived. The law does not endeavor to preserve any vain privileges and such a privilege as would allow a witness to answer a principal criminating question and refuse to answer as to its incidents, would be worse than vain; for while it could not help the witness, it must inevitably injure the party, who is thus deprived of the power of cross-examination to test the credibility of a person who may, by avoiding it, indulge his vindictiveness or corrupt passions with impunity. * * * And the further consideration is also recognized that a witness has no right, under pretense of a claim of privilege, to prejudice a party by a one-sided or garbled narrative."

The case of an accused in a criminal trial differs, however. He has the privilege of refusing to take the stand and may be protected from answering even a single question. If he voluntarily takes the stand to testify as to any facts, he waives his privilege as to all relevant facts. He cannot be compelled to testify in the case at all, as can the ordinary witness. The privilege of the defendant is against giving any testimony, while that of the ordinary witness is to exercise his privilege later when some criminating fact is demanded. The following summary of the rule as stated in a very recent decision in this State is pertinent:

"The constitutional provision that a person shall not be compelled to be a witness against himself is as broad as the mischief against which it seeks to guard. The meaning of the constitutional provision is not merely that a person shall not be compelled to be a witness against himself in a criminal prosecution against himself, but its object is to insure that a person shall not be compelled, when acting as a witness in any investigation, to give testimony which may tend to show that he himself has committed a crime."

Certain statutes modify the general rules respecting the privilege to refuse to testify, but they do not interfere with the rights bestowed by constitutional provision for the reason that these statutes also provide for an immunity from prosecution based on testimony brought out on such compulsory examination. Examples of statutes of this sort are found in the Sections of our Penal Law relating to testimony as to bribery, corruption, gambling and conspiracy. A typical provision of this sort is Section 584, relating to the privileges of witnesses in conspiracy prosecutions, which is as follows:

"[W]itnesses' privileges: No person shall be excused from attending and testifying, or producing any books, papers or other documents before any court, magistrate, or referee, upon any investigation, proceeding or trial, for a violation of any of

the provisions of this article, upon the ground or for the reason that the testimony or evidence, documentary or otherwise, required of him may tend to convict him of a crime or to subject him to a penalty or for forfeiture; but no person shall be prosecuted or subjected to any penalty or forfeiture for or on account of any transaction, matter or thing concerning which he may so testify or produce evidence documentary or otherwise, and no testimony so given or produced shall be received against him upon any criminal investigation, proceeding or trial."

The privilege of immunity, likewise, is a privilege which may be waived, and the manner of waiver is set forth in Section 2446 of the Penal Code which provides:

"*Waiver of immunity.* If it be provided by this chapter or any other general or special law that a person shall not be prosecuted or subjected to any penalty or forfeiture for or on account of any transaction, matter or thing concerning which he may testify or produce evidence, documentary or otherwise, or that testimony so given or produced shall not be received against him upon any criminal investigation, prosecution, or proceeding, such person may execute, acknowledge and file in the office of the county clerk a statement expressly waiving such immunity or privilege in respect of any transaction, matter or thing specified in such statement and thereupon the testimony of such person or such evidence in relation to such transaction, matter or thing may be received or produced before any judge or justice, court, tribunal, grand jury or otherwise and if so received or produced such person shall not be entitled to any immunity or privilege on account of any testimony he may so give or evidence so produced."

Recent events have focused public attention upon the clause above quoted. Frequently in certain investigations that have been initiated in the past year or so, public officers have refused to sign a waiver of immunity in connection with testimony sought to be elicited from them by the investigating authorities.

At the last session of the Legislature, a bill was introduced to meet this situation. The essential part of the bill in question read as follows:

"The acceptance hereafter by any person of a public office or position shall, in any and every investigation, hearing, proceeding and trial, whether civil or criminal, constitute a waiver of his constitutional privilege against self-incrimination in relation to any act or omission as such public officer and in relation to any act or omission effecting his appointment, nomination, election or promotion to or in such public office or position. The term public officer as used in this section shall be deemed to include a deputy, clerk, assistant or other subordinate of a public officer, or any person appointed or employed by or in the office of a public officer."

While the bill failed of passage, it doubtless will be reintroduced in the next session of the Legislature. Its constitutionality has already been assailed, but the proponents of the bill contend that there is no infringement or waiver of constitutional rights for the bill does not purport to be retroactive, and that it does not infringe upon the constitutional rights of any individual since it is attached as a condition to the voluntary acceptance of a public office. Of course, the question of constitutionality of this bill will never be tested by the courts unless the bill should become a law.

ALLEGED NEGLIGENCE IN NEEDLE BREAKING

A young man employed in an automobile repair shop while working about a car received an injury above the left eye, caused by a piece of spring steel snapping back and striking him. He was sent to the office of the defendant doctor for treatment, and the defendant not being in, another doctor associated with him cleaned the wound and dressed it. The next day the patient returned and the defendant applied a clean dressing and gave him a hypodermic injection of tetanus antitoxin in the arm. While the needle was being inserted the patient jerked his arm with the result that the needle broke. The doctor tried to remove it, but failed, and when he found it could not be readily removed he gave the patient a note to take to a nearby *x*-ray specialist with instructions to have an *x*-ray taken of the arm, which was done and the plate disclosed the presence of the needle.

At this point in the matter, the insurance carrier of the plaintiff's employer requested that the case be turned over to another doctor designated by them. This was done and the said doctor removed the needle after performing two operations for that purpose.

An action was started by the patient charging the defendant with malpractice in inflicting an injury upon his arm. In addition to a denial of any negligence, the fact was pleaded as a defense on behalf of the doctor, that the plaintiff had received compensation for his injuries under the Workmen's Compensation Act. The plaintiff failed to press the matter for trial and after a considerable period of time had elapsed, a motion was made on the defendant's behalf to dismiss the case for the plaintiff's failure to prosecute the same. This motion was granted, disposing of the suit in favor of the doctor.

NEWS NOTES

LEGISLATION

BULLETIN NO. 12—APRIL 13, 1931

The legislature adjourned sine die Friday at 8:30 P. M. Nothing of interest to us happened after the bulletin was issued that day.

The amended Wicks-Hutchinson bill carrying the provision for the three tuberculosis hospitals and the other Wicks-Hutchinson bill authorizing the transfer of Ray Brook and Haverstraw Hospitals to the Department of Health, passed both houses and now rests with the Governor

In the Senate the following twelve Senators voted for the chiropractic bill:

Mr. Burchill
Mr. Campbell
Mr. Fearon
Mr. Feld
Mr. Frost
Mr. Hickey
Mr. Kirkland
Mr. McCall
Mr. McNaboe
Mr. O'Brien, H. L.
Mr. Westall
Mr. Williams

There follows a statement of the vote by which the osteopaths failed to take their bill from the table in the Assembly:

Ayes—75

Mr. Abbott
Mr. Alterman
Mr. Austin
Mr. Bernhardt
Mr. Breen
Mr. Burke
Mr. Byrnes
Mr. Cahill
Mr. Catchpole
Mr. Condon
Mr. Cuvillier
Mr. Davis
Mr. Dineen
Mr. Downs
Mr. Dunmore
Mr. Eberhard
Mr. Falk
Mr. Gamble
Mr. Garnjost
Mr. Goodrich, H.E.
Mr. Goodrich, M.E.
Mrs. Graves
Mr. Hanley
Mr. Hartshorn
Mr. Hathaway
Mr. Hayes
Mr. Hewitt
Mr. Higgins
Mr. Holley
Mr. Horn
Mr. Jenks
Mr. Kahan
Mr. Kantowski
Mr. Killgrew
Mr. Latour
Mr. Lamont
Mr. Lewis
Mr. Lynde
Mr. Mandelbaum
Mr. Marks
Mr. McKay
Mr. Merriam
Mr. Mittler
Mr. Moffat

Mr. Mulligan
Mr. Munsil
Mr. Nathanson
Mr. Nutt
Mr. O'Reilly
Mr. O'Rourke
Mr. Palmer
Mr. Pollard
Mr. Post
Mr. Pratt
Mr. Robinson
Mr. Roulier
Mr. Samberg
Mr. Saunders
Mr. Schanzer
Mr. Schwartz
Mr. Schwartzwald
Mr. Smith, W.F.
Mr. Streit
Mr. Taylor
Mr. Thompson
Mr. Turner
Mr. Whittaker
Mr. Winters
Mr. Zimmerman

It should be said, in explanation of this vote, that many legislators are good sportsmen and believe that every bill should have a fair chance, so when the first vote on the osteopathic bill was taken, you will recall we reported Mr. Cuvillier voted to have it recommitted but his motion was lost by a substantial majority. When the bill itself was voted upon, however, it was defeated. The same spirit prompted quite a number of Assemblymen to vote in favor of taking the bill off the table at this time. Had that motion prevailed without doubt those who had voted against the bill before would again have registered their vote in the same manner; so that it must not be concluded that all who are recorded here as having voted to take the bill from the table would have voted for its passage if they had had the opportunity.

HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY,
Committee on Legislation.

PRIZE ESSAYS

Attention of the members is called to the Merritt H. Cash and Lucien Howe prizes of One Hundred ($100) Dollars each which will be open for competition at the coming Annual Meeting of the Medical Society of the State of New York for the best original contribution to the knowledge of surgery, preferably ophthalmology, and for the best original essay on a medical or surgical subject.

Competitors for these prizes offered through the State Medical Society must send in their essays at once to Dr. Thomas H. Curtin, Chairman of Committee on Prize Essays, 391 East 149th Street, New York City.

SECOND DISTRICT BRANCH

The twenty-fourth annual meeting of the Second District Branch was held at the Garden City Hotel on the evening of April 14th, with the President, Dr. C. H. Goodrich of Brooklyn, presiding. The meeting was preceded by a dinner of the members and their guests, who included Dr. W. H. Ross, President of the State Society; Dr. D. S. Dougherty, Secretary; Dr. John A. Card, Speaker of the House of Delegates and Chairman of the Insurance Committee; Dr. J. E. Sadlier, the Chairman of the Public Relations Committee; Dr. Charles Gordon Heyd, Treasurer; Dr. O. S. Wightman, Editor-in-Chief; and the Executive Officer, Dr. J. S. Lawrence.

Dr. Louis A. Van Kleeck, Nassau, was elected President; Dr. Thomas C. Chalmers, Queens, First Vice-President; Dr. William J. Tiffany, Suffolk, Second Vice-President; Dr. Alec N. Thomson, Kings, Secretary and Treasurer.

Dr. Chalmers introduced a resolution regarding the invasion of the rights of the State of New York to regulate the practice of medicine in its own borders through the Volstead Act, which deprives the physician of his right to the free exercise of his judgment. This resolution was passed unanimously.

Dr. Van Kleeck, the newly elected President, was introduced to those present and in a few well-chosen words stated that he hoped to be able to measure up to the remarks made by Dr. Ross in his discussion of the problems of the District Branch, its purpose and its opportunities.

The members then heard from Dr. Card with regard to insurance, and Dr. Wightman regarding the State Journal, and then listened to a brief scientific address presenting some new facts in therapeutic applications, based upon our increased knowledge in physiologic chemistry relative to the use of glucose in relation to liver disease.

Dr. Charles Gordon Heyd, President of the New York County Society, delivered an illuminating address upon the economic background of the practice of medicine.

The Presidents of the four county medical societies of the Districts, Kings, Queens, Nassau, and Suffolk, presented the following reports of their Societies' activities during the year:

THE MEDICAL SOCIETY OF THE COUNTY OF QUEENS

Our Society spent the first year enjoying the benefits of our new home, which was the seat of most of our activities in respect to meetings of the Comitia Minora, the stated meetings, and most all of the Committee work. We felt strange in such commodious appointments and even today, are not yet accustomed or acclimated to the intricacies of operation.

We enjoyed being the host on April 1st, 1930, to the 1930 District Branch Session and appreciated the attendance of those men coming out to pay their respects.

In the past year we held seven stated meetings at our building, including the annual meeting and two other outing meetings at golf clubs. In June we held a combined meeting with the Medical Association of the Greater City of New York, at the Clearview Golf Club, Bayside, and one combined with the Queensboro T.B. & Health Assn., at the Oakland Golf Club in September. Our attendance averaged 33% of our membership, which is now about 546, having increased about 50 since last year.

Our Comitia Minora met about eight times during the year and our Board of Trustees as frequently. We publish a printed monthly bulletin of twenty-four pages for announcements to the members. The problem of financing and operating our $250,000 building project occupied much of the time of the Board of Trustees and the Comitia Minora. It has been a real live problem for our busy doctors to face; this coming at a time, too, when the world faces an economic crisis is lamentable. We fell behind in the collections of loan pledges and were forced to raise the dues of the members $10 more per year. We are thankful so far, not to have been forced to raise an outside mortgage but were able to maintain a good credit by borrowing substantially from our bank.

Our meetings were usually varied and of general medical science character, but one meeting on juvenile delinquency was opened to the legal profession, the public and the membership. The Society held an exhibit of its scope of work at the recent Queensboro Chamber of Commerce Exposition. Our Post-Graduate Education Committee offered a number of Friday afternoon talks to the members on many topics and provided a series of courses in surgery, obstetrics, medical diagnosis, pediatrics and orthopedic surgery. The committee was supported actively and financially by the Queensboro T.B. and Health Assn. Last month it collaborated with the Committee to sponsor a largely attended special meeting addressed by Dr. Geschikter, assistant to Dr. J. Bloodgood of Baltimore, on the subject of cancer control.

The Queensboro T.B. and Health Assn. has again continued this year its liberal support of the other Graduate Medical Education work of

the Society and has provided the important tuberculosis and public health periodicals published throughout the world for our library. The Association also made the initial grants for proper facilities for the work of our Public Health and Public Relations Committee. During the past year it again gave its wholehearted cooperation to these committees in the promotion of the physical examination of entering school children by private physicians throughout the borough, with the result that Queens leads all the boroughs of New York City with over 54% of the 12,000 such children presenting certificates from private physicians. It has been estimated that these examinations with the corrective work that followed, brought the physicians of the borough a good income, not to mention the vast improvement in the future health progress of these children.

The Queensboro T.B. and Health Assn. also contributed $876.40 in 1930 toward securing books for our library, and also gave $150 toward a joint meeting with the Medical Society of the County of Kings and the 2nd District Branch Dental Society, which meeting was held in Brooklyn on March 10, 1930.

Our Public Health and Relations Committee formally organized and intrenched itself in a special committee room in the building and has conducted hard work along the lines of public health survey, annual health examination, examination of pre-school children, diphtheria immunization work, regulating the practice of physiotherapy, care of the T.B. patient, private hospital control, maternal and infant mortality, cancer control, and control of blood donors. The Queens County Cancer Committee, affiliated with the American Society for the Control of Cancer, now maintains an office and paid secretary in our building for the prosecution of cancer work.

Our library has not as yet been functioning, partly due to delayed equipment and furnishings and partly to lack of available funds. Our Society has requested the cooperation of the Queensboro Public Library by offering to it our library facilities, provided the City would operate the same at its expense. This question is now under consideration by the Board of Estimate and Apportionment. Our library contains at least 10,000 volumes and our magazine room has a number of current journals; but only the latter are in use by the members, the books not yet having been catalogued, lacking a librarian.

Our Legislative Committee has worked and secured passage of a bill by the New York State Legislature, both Assembly and Senate, providing a tax exemption of $150,000 for Queens, the same as enjoyed by New York and Kings Counties. This bill is now before the Governor awaiting signature.

The Society loaned and advanced the sum of $2,000 to an interlocked corporation, "The Queens Medical Society Business Bureau, Inc.," organized to do business for the Society and the members. Its principal work has been the collection of accounts of physicians, and a nurse's registry. Commissions for collections have been earned, but so far has not been profitable enough to declare dividends, but with the personal guidance of a new energetic manager we have prospects of dividends this coming year.

Other varieties of business are under consideration. One social event, a public Bridge benefit under the auspices of the Bureau was a success, netting the sum of $800, thanks to the help of the ladies of the Society.

The Society feels that it has been unusually alive to its function in the medical world in Queens and expects to enlarge its scope of work, particularly when the burden of the budget has eased up sufficiently to permit its officers to think along constructive lines rather than its financial obligations.

Respectfully submitted,
ALBERT L. VOLTZ, M.D.,
President, Medical Society, County of Queens.

THE MEDICAL SOCIETY OF THE COUNTY OF KINGS

For a number of years my predecessors in the Presidency of the Medical Society, County of Kings, have, in one phraseology or another, reported nothing markedly new—but that the year has shown progress.

We have continued to foster our relationships with the community and in this regard our activities, while about the same in principle, are becoming more and more complex in detail.

We have carried on as in the past our work in graduate education through our *Bulletin*, through our scientific papers at our stated meetings, through our graduate education courses, through our twenty Friday Afternoon Practical Clinical Lectures and through the maintenance of our Library.

Perhaps the outstanding feature of the year with regard to community relations has been the formation of a Five-County Society Conference Committee which hopes that 1931 will show real progress in the coördinating of public relations that apply to all the County Societies in the Greater City.

We in Kings and Queens have many problems that are similar. In these problems we must combine our activities more with the other three

Counties of the Greater City than with the other two Counties of the Second District Branch.

Our work in connection with the health examination, with the diphtheria program, with the examination of children entering school for the first time, with the health promotion work in Continuation Schools, with the visiting nurse organization and similar activities dealing with city-wide official and unofficial organizations requires greater and ever greater work by the coordinated Five-County Societies composing the City of New York.

Perhaps the one item of activity most outstanding has been the marked interest on the part of the profession in the activities of our Committee on Medical Economics. This has resulted in the holding, since the first of the year, of four open meetings of this Committee. These meetings have been well attended, have discussed many items and have been truly valuable in guiding the Committee in its work.

In addition to medical economics and in part a feature of the general problem is the increasing demand upon the County Society for general information. Nearly two thousand inquiries are received annually by Kings County regarding physicians, various medical procedures, charlatanism, institutions, and a miscellaneous group of inquiries from physicians and laymen.

This is a valuable service which it would seem that the County Societies must continue to provide.

W. D. LUDLUM, *President.*

THE SUFFOLK COUNTY MEDICAL SOCIETY

While the objectives of the Suffolk County Medical Society are similar to those of the other Societies of this 2nd District Branch of the State Medical Society, their methods of accomplishment must of necessity differ because of the geographical location of the Society and because of the extensive rural districts separating its various urban centers of population. The county is 75 miles long and 20 miles wide. The by-laws, for these reasons, provide for only two meetings a year, one in October and one in April, and it is therefore impossible to conduct the educational post-graduate lectures and the intensive public health programs in the meetings as is done by the other Societies of this district branch.

Under these circumstances it is felt that our two meetings should and do best serve our members and our county by formulating the policies and programs to be carried out by committees and then hearing and discussing the reports of these committees in our morning business sessions. Our meetings are always dinner meetings which afford opportunities for social intercourse and the informal discussion of various policies and programs for county cooperative medical work. The afternoon sessions are devoted to scientific programs which usually include visiting speakers on subjects of importance to our common county society interests.

The Comitia Minora has held monthly meetings throughout the winter and has invited the members of the standing committees of the Society to attend. In this way the Society functions to progress and integrate its policies and programs of Public Health, Education, Public Relations, Child Welfare, Legislation, and Medical Economics in cooperation with the State Society programs.

The monthly News Letter has been of the greatest value in communicating the activities of the Society, of the Comitia Minora and of the various committees to all of the members of the Society and to all of the various welfare and educational organizations and public officials of the county. It has also reported on the general health conditions in the county, the visits of town nurses, the activities of the Suffolk County Tuberculosis and Public Health Association, and the Child Welfare Board. In this way it is serving to orient and guide both the medical and the lay community in the furtherance of all of our public health objectives. The chairman of the Publication Committee is the County Commissioner of Health.

Our Legislative Committee has followed closely the various bills involving medical practice and social welfare introduced into the Legislature and the Chairman has made several trips to Albany to attend State Society Committee meetings. These bills have all been reported to and discussed by the Comitia Minora and approval or disapproval has been registered with the Legislative representatives.

The Public Health Committee has entered upon a program of preventive medicine along the lines of (1) measles prevention, (2) cancer elimination, especially popular instruction and (3) tuberculosis prevention, especially a continuation of the study of the incidence of tuberculosis among the families and children of patients in the infective stage of the disease. The Chairman of this Committee is Dr. Frank Overton who is the active Secretary of the Suffolk County Tuberculosis and Public Health Association and the Executive Editor of the NEW YORK STATE JOURNAL OF MEDICINE. Dr. Arthur T. Davis, County

Health Commissioner, and Dr. Edwin P. Kolb, Superintendent of the Suffolk County Tuberculosis Sanitarium and Secretary of the Suffolk County Medical Society, are also members of this committee, thus assuring the active carrying out of this ambitious program.

The work of the Medical Economics Committee is especially gratifying as it shows concrete results from its conferences with the Commissioner of Welfare of Suffolk County and the Superintendents of the various hospitals in Suffolk County. The better understanding of medical viewpoints by the Commissioner and of various welfare limitations by the physicians and superintendents has led to a cooperative arrangement regarding proper fees and necessary care which seems satisfactory to all concerned and which will certainly make available more prompt relief to individuals needing help under the new welfare laws.

The efforts of the Suffolk County Medical Society in promoting civic medicine are generally recognized by the citizens of the county who show their appreciation by their hearty cooperation and support of its health programs.

The County Health Department is an outstanding example of this support by the public. It is the first County Health Department organized as a result of action by a County Society, and has now been in operation over two years. Its satisfactory service and organization have attracted the attention of neighboring and distant states. It now has a veterinary division, the first of its kind to be established in the United States under a County Board of Health and therefore medically controlled. This division is conducting extensive investigations of diseases which can be conveyed from animals to men, such as streptococcic mastitis and contagious abortion in cows and rabies in dogs.

Our Society is especially proud of the fact that the efforts of one of its members, Dr. Wm. H. Ross, in advancing organized medical activities in our county and in our state, have been recognized by the State Medical Society in electing him to its highest office. We are heartily supporting him and his policies as President of the State Society and trust that this 2nd District Branch will join us in making his administration an outstanding one for the better organization of medicine in New York State.

WM. J. TIFFANY, *President.*

NASSAU COUNTY MEDICAL SOCIETY

During the year 1930 the Nassau County Medical Society has devoted its energies to two major problems:—the acquisition of a county hospital and the management of a diphtheria toxin-antitoxin campaign.

For several years our need for a county hospital for the care of communicable and chronic disease has become steadily more pressing. This year the County Medical Society assumed the responsibility of conducting the campaign which was successful at the November polls by a vote of eight to one. The Society devoted much time to presenting the hospital proposition to the public and was gratified by the splendid result. Not only were we successful in obtaining the necessary appropriation but we also are represented on the Board of Managers by a member elected by us. In addition to this, at the request of the Board of Supervisors a committee of three members was appointed to assist this Board in solving problems of a medical nature. The President of the Board of Managers has repeatedly requested that the Society must participate in the affairs of the hospital, which gives us a responsibility we are glad to assume.

The county diphtheria toxin-antitoxin campaign was planned and carried out by the Society and its members. The executive secretary and the Public Health Committee zoned the county and requested each physician to set aside definite hours when those unable to pay for the immunizations could receive them free of charge. Considerable publicity was given this idea and many children, otherwise excluded, were thus protected. In 1929 and 1930, 16,075 children were immunized. The infant and pre-school child —those requiring most this protection—still represent only 32% of the total number. In continuing our campaign we plan to direct more effort toward this younger group. In 1928, there were twelve deaths from diphtheria in Nassau County. In 1929, there were ten and in 1930, four. The number of cases has diminished proportionately.

The success of these two campaigns, and the numerous contacts established, have unquestionably benefited our public relations. The ready cooperation we have received from various lay groups demonstrates a fact which may prove of some importance, viz., whenever a group of physicians show their ability and willingness to handle health problems, they will unquestionably be given the opportunity to do so.

Internally, our Society has had a good year. A spirit of ethical good feeling and friendliness has been apparent. The meetings have been well attended, and the members have shown a willingness to help in the execution of Society affairs. In keeping alert to the needs and trends of the day, we have tried not to forget that medical idealism is the best antidote for medical unrest.

BENJAMIN R. ALLISON, *President.*

THE DAILY PRESS

SPRING SONGS

There is natural history, if not medicine, in the spring songs which greet the ear of the rural doctor on his evening calls; and there is, in addition, poetic literature in the following reference to those sounds made in the following editorial in the New York *Herald Tribune* of April 17:

"The pinkletinks are tinkling out on Martha's Vineyard, as is duly reported in 'The Vineyard Gazette,' whose editor knows that the doings of the piscatorial and amphibian and gallinaceous citizens of the island which Bartholomew Gosnold discovered in 1602 are as significant as those of its humans.

"But what are pinkletinks? 'The Vineyard Gazette' quite properly assumed that Vineyarders would understand. A reader in far-off Manhattan suspected that they were what superscientists call 'Hyla pickeringii' and country boys on the mainland know as 'spring peepers.' He wrote and inquired; the Vineyard editor confirmed the suspicion adding that it had been suggested that Shakespeare based 'The Tempest' upon the tales of Gosnold's men, that the song of the pinkletinks was the cue for Ariel's song, and that the goblin dances and uncanny noises of the Vineyard heath hen suggested Caliban and the grosser spirits of Shakespeare's enchanted island.

"The theory seems to us, on rereading 'The Tempest,' more than probable. Authorship of Shakespeare's plays has been ascribed to other men on far less substantial evidence than the play yields to buttress this theory. 'How lush and lusty the grass looks! How green!' says Gonzalo; Antonio replies: 'The ground indeed is tawny,' and Sebastian adds, 'With an eye of green in it.' The description of the Chilmark downs could hardly be more accurate, unless indeed one read on to the phrase describing 'bosky acres' and 'unshrubbed domes, rich scarf to the proud earth.' That 'hollow burst of bellowing, like bulls, or rather lions,' which alarmed Sebastian—does it not suggest that Gosnold's men heard the booming of a thousand love-sick heath hens? The heath hen then was nameless, and it was natural for Shakespeare to refer mistakenly to the 'peacocks' which 'fly amain.' Caliban's comment is definitely reminiscent of the notes of Vineyard pinkletinks:

'The isle is full of noises,
Sounds, and sweet airs, that give delight, and hurt not.
Sometimes a thousand twanging instruments
Will hum about mine ears, and sometimes voices
That, if I then had waked after long sleep,
Will make me sleep again.'

If Shakespeare was not inspired by stories of the Vineyard off Cape Cod, he must at least have known some island almost as lovely. Where else do people have the instinctive poetry in their souls to give such names as 'beetlebung-tree' to an ironwood and 'pinkletink' to a spring peeper?"

HAIR WAVES IN THE ORIENT

When the Oriental women go in for waving the straight black locks of hair, there is a prospect that American Medicine will be sought with equal eagerness. The New York *Times* of April 20 has the following editorial description of a rising demand for the latest American style of hair dressing:

"One might suppose that in Japan and China, where hair is allowed to grow naturally and fashionably straight, there would be no demand for a permanent waving machine. Yet an American girl, with a one-heater device and a keen desire to see the Orient, found more than enough clients who longed for curly hair to provide work and traveling expenses for herself and her mother.

"Business came so rapidly in Japan that an order was soon sent for a larger machine. Wherever the lure of unseen countries took the journeymen hair-dressers, trade followed the permanent wave. Many who asked for curly locks were the wives of European and American business men and planters stationed in far countries. But numerous Japanese and Chinese women also were delighted to submit their long, black, glossy tresses to the 'miracle' machine."

A NEW MARATHON VICTORY

Athens was saved in 490 B.C. by a Greek army entrenched at Marathon in a defile against a background of hills in which the horsemen of the Persian invaders could not maneuver; and now that defile is to save Athens from a water famine, according to the New York *Times* of April 19:

"Not far from where Miltiades overcame the Persians a reservoir has been built of such capacity as to insure an adequate supply of water for the city that has never had enough. The course of the water that will run continually from Marathon to Athens is probably a more direct and easier one than Pheidippides followed, 'over the Parnes ridge,' 'clambering gully and gap'; for it passes through a tunnel under the mountains a part of the way and then descends through many pipes to Athens and the Piraeus.

"It is pleasing to note that an American company has carried to completion this project, which is to be put to use in the coming month. To it the award was made by the Hellenic Republic, successor of Solon, who as long ago as 600 B. C. was troubled by inadequacy of the water supply and vigorously regulated its use. The modern engineering achievement deserves the meed of such praise as the old Greek poets could best have phrased. And the patriotism of Americans should 'gain force upon the plain of Marathon.' As it is, there is an appropriate architectural classical tribute in the structure that stands at the base of the dam in Marathon—a reproduction of the Athenian Treasury at Delphi. Since the original was erected from the spoils of the victory at Marathon it is poetically fit that the memory of it should be kept where glorious occasion was given for that priceless memorial—a treasury whose sole treasure is its beauty—and where new occasion is given by this fresh victory."

BROADCASTING FROM AIRPLANES

The Noise Abatement Commission of New York City has public sentiment behind it; but no sooner is one source of noise removed than another springs up. One of the worst of the new noises is described in the following editorial in the New York *Herald Tribune* of April 13:

"Gina Lombroso has just written a book called 'Tragedies of Progress.' One of the most ghastly tragedies, which Miss Lombroso failed to mention is the discovery that it is possible to pour noise out of an airplane and flood a city with it. Broadcasting from the air, it seems to us, is an unmitigated nuisance; if the police have power to stop the blare of loud-speakers which cannot be heard a block away, they surely have the right to stop a winged monster which, from a height of 2,500 feet, pours out its ugly racket.

"The manager of the corporation which exploits these noisy pests assured the police, when Dr. Christian Reisner complained of one of them, that his pilots had strict orders to avoid churches and hospitals. Nonsense! As well tell an automobile to drive through the city without passing such buildings. The city is sprinkled with them.

"A time may come when even private radios will be far more strictly policed and controlled than they are today. A single home radio blaring into a row of quiet back yards may be even more destructive to city nerves than a commercial machine competing with automobile traffic and the roar of the Elevated. Such regulation, however, may require preliminary education; there can be no dispute about the pestiferous character of noise machines pouring their ugliness out of the heavens into street and yard with utterly indiscriminate intrusion and vulgarity."

ACCURACY OF SMELL

While a dog and many other lower animals have wonderfully sensitive noses, yet human beings are easily misled in their interpretation of odors. The New York *Herald Tribune* of April 5, discussing the subject, says:

"Psychologists found long ago that not a nose in a thousand could distinguish roses from one another by scent alone: reminiscent and nostalgic as it is, the nose is a notorious liar. Every cook understands how palates can be fooled. Many a concertgoer has been shocked at himself after competing in a music identification contest. In truth, a fine ear for music is often claimed in unconscious snobbery. When Gigli, unknown, passed singing through the kitchen of the Mayflower Hotel in Washington not long since, the chef exhorted him to 'Shut-up that noise.' Last autumn Jacques Gordon, Chicago violinist, played before a lorgnetted Boston audience, which lavished applause. Next day he made himself up as an aged vagrant, took the same $40,000 three-hundred-year-old Stradivarius, and played the same selections on the street, near fashionable churches, attended by members of his audience of the night before. Nobody noticed such music. He earned $1.27 for the day."

OUR NEIGHBORS

CHIROPRACTIC BILL IN TEXAS

The official Medical Journals of several states contain racy accounts of chiropractic discussions in the State Legislatures; and the following from the March number of the Texas State Journal of Medicine is certainly interesting from both human and humorous standpoints:

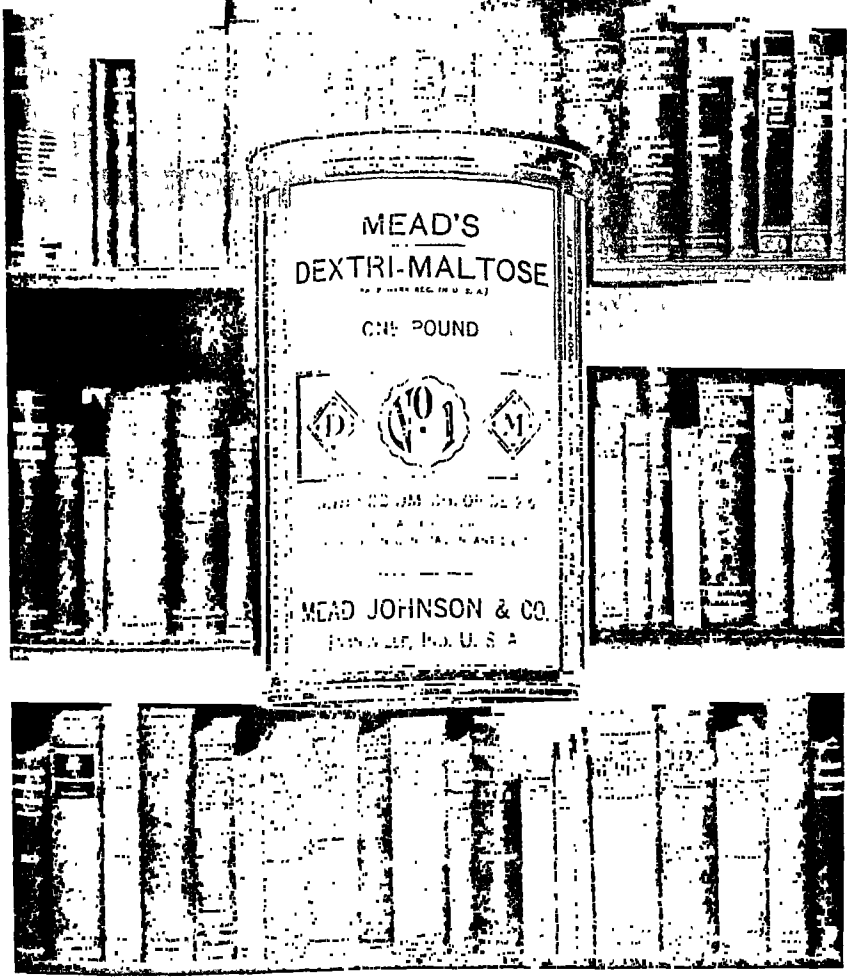
"THE CHIROPRACTIC BILL. A hearing on this bill (H. B. 202) was held by the Health Committee of the House February 25. The hearing early gave promise of being of the usual hectic, knock-down, drag-out sort. The committee, because of the constantly increasing size of the crowd, changed its location three times, winding up in the main auditorium. Mr. Still, the Christian Science Committee on Publication for Texas, was a very interested spectator. Just wherein lay his interest we did not determine. He had nothing to say.

"We regret that we cannot give a full account of the very interesting discussion that ensued. We have a rather full longhand report of the discussion, from which we take the liberty of quoting the views of the proponents of the bill:

"Mr. C. E. Farmer stated that it was intended primarily to control the quacks in the profession of chiropractic and raise high the standards of that practice. The bill is bitterly opposed by the medical doctors, notwithstanding the chiropractors did not oppose the two measures intended to raise their own standards. The chiropractors have kept the faith (as if there had been any faith to keep!). The definition of the practice of medicine in the Medical Practice Act, which is a go-getter and covers anyone who tries to relieve anything by any method whatsoever and charge for it, makes it necessary that the chiropractors have a law of their own. Mr. Farmer then dilated upon his favorite subject, which is his championship of the downtrodden.

"He called attention to the large number of medical doctors present, evidence of the intentions of the medical profession to overwhelm the committee. (He did not at this time see the much larger number of chiropractors, their sympathizers and victims.) But, after all, there are thousands and thousands of people of Texas who are receiving help from the chiropractors (applause). Texas still holds the battlefields of San Jacinto and the Alamo. Forty states now recognize chiropractic, and it is a well-known fact that in Texas chiropractors cannot be convicted of the charge of practising medicine because public sentiment is with them. The few convictions that are secured could not be made to stick in the higher courts. (Applause.) The Legislature is branding chiropractors as outlaws by denying them recognition.

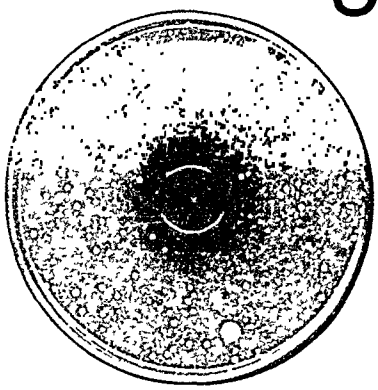
" 'Dr.' Dean, head of a chiropractic school, rose nobly to the occasion in rather a choleric and tiresome discussion of the merits of the bill and the needs for such legislation. He started out by saying that he was well acquainted with the bill, this being the fifth time he had had occasion to discuss the bill with the legislators. He said the chiropractors were not asking for sympathy. They were asking for and hoped to get a majority favorable report on the bill. The chiropractors are merely asking the state to give them legal recognition in order that they may practice their profession without prosecution, and charge for their services.



"All the chiropractors want to be allowed to do is to find the fault responsible for the illness, and then correct it. (Very simple, indeed.) Having risen to this height, the speaker did not hesitate to say that chiropractors constitute the only group in all the world of healing which does this correctly."

CHIROPRACTIC FIGHT IN COLORADO

Let no one be deceived into believing that chiropractic is dead. The passage of a model practice of medicine act is by no means a death blow to cults, as is demonstrated in New York State, where one branch of the Legislature has just passed an act legalizing the practice of chiropractic. Colorado has been through a chiropractic fight, as is shown by the following description in the April issue of Colorado Medicine:



"Though the bill vitally concerned the State Board of Medical Examiners, political
resulted in its being referred to
on Education rathe to the
Medical Affairs a H.
mittee on Educa
and finally repo f
vote of s o th.

BACKGROUND

THE use of cow's milk, water and carbohydrate mixtures represents the one system of infant feeding that has consistently, for three decades, received universal pediatric recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Mead's Dextri-Maltose.

(*Continued from page* 594)

"Numerous amendments, removing from the bill such features as were too openly vicious even for the anti-medical-minded legislators to stomach, were offered by the bill's sponsors. First was removed the clause which would have permitted chiropractors to practice minor surgery. (Just who would have drawn the line between major and minor surgery?) Then a definition of chiropractic was inserted, supposedly to pacify osteopathic opposition to the bill. Then two other amendments to pacify the osteopaths and gain their support of the measure. Then an amendment to prohibit the chiros from 'dispensing or administering' drugs. The original bill had prohibited them only from 'prescribing' drugs. Then an amendment stiffening the restrictions around granting reciprocity to chiropractors from other states. Several amendments offered by opponents of the bill were voted down. But finally an amendment by the medical side of the House was adopted (with a two-vote margin) prohibiting chiropractors from using *x*-ray or electricity. Then another by the medical side was admitted, this time eliminating the bill's proviso that chiropractors might practice 'chiropractic as taught in chiropractic schools and colleges.' Under this proviso the cult schools might have established three-month or three-week courses in fractures, for instance, and thereby have legislated for Colorado and have given all Colorado chiropractors the right to set fractures whether they had ever studied the subject or not.

"After each amendment was adopted, spokesmen for the chiropractic group approached the Executive Secretary of the State Medical Society or those legislators opposing the bill and asked if this would not now suffice to withdraw the opposition. It was evident the cultists were willing to give up much of the bill if only they could get that separate board of control, if only they could get those powers that would result in their extending their practice with no one to place a limit except their own hand-picked board of examiners.

"After all amendments were in the bill a motion from the medical side sought what should have been done by the Speaker of the House at the opening of the assembly—reference of the bill to the Committee on Medical Affairs and Public Health. The motion carried by two votes.

"Then began a two-hour parliamentary battle which newspapers characterized as the hardest fight so far in the three months of the legislative assembly. The chiropractic side many times attempted to adjourn the House until the next day, in the hope that some votes could be changed overnight. Both sides many times forced a 'call of the House,' whereby the sergeant-at-arms would send out through the cloak rooms, corridors, and even into down-town Denver, to force

absent members to come back despite the waning supper hour and be present to vote on the next motion.

"The medical side finally entered a motion to kill the bill definitely and thus obviate even that slim chance that the Medical Affairs Committee might be wheedled into giving the bill another chance. The vote showed twenty-nine to twenty-nine. Under the House rules the Speaker (who favored the chiropractors) votes as does any other member and so does not have the power to break a tie. Absentee votes had to be found. Two were brought in and the vote stood thirty to thirty. Another was brought in, and sought to avoid voting. Rep. Wayne Aspinall (Mesa) threatened to prefer charges if the member did not vote. He cast a vote to kill the chiropractic bill and the fight was won."

CHIROPRACTIC IN DELAWARE

Delaware is another State in whose legislators listened to the siren voice of the chiropractor and passed the bill demanded by the cultists. The March issue of the Delaware State Medical Journal says:

"The Chiropractic Bill went through the House by a thirty-three to two vote, and through the Senate with but two negative votes. Why was such a thing done by a group of people elected to protect and serve the interests of the State? A number of explanations might be made. If they were ignorant of the subject, then it would seem, before creating such a health act, those responsible for the results would consult the State Medical Society, or the State Board of Health, which latter would conflict with the claims and practices of chiropractic, before legalizing such a practice. The opinion of many was that there was no use to try to do anything about it because of the course of actions already decided upon by a majority of the legislature. Even though we might not have made the situation as clear as we should, and important facts and circumstances were not brought out and emphasized, the truth of the matter is the action of the legislature was dangerous.

"The State has reason to be thankful that we have a Governor who has intelligence enough to understand chiropractic and courage enough to act in the interest of his fellow citizens of the commonwealth. We may not have a governor of that type at another time.

"What can be done to guard the state against dangerous inroads by cultists and faddists? It is surprising how many of the more intelligent, better educated and successful individuals know so little about such things as chiropractic—those who can see and are willing to see when shown. As for some of the others we feel sometimes, what is the use! But of course from those who

have received more, more is expected. So the medical profession should see to it that the public become better informed in medical matters.

"If one cult is recognized others will appear and the best way to handle them and the best way to guard against them is for the state to have a Basic Science Law. It would perhaps be better, as Dr. Charles Mayo has suggested, if we could have 'national educational requirements for all people who are permitted to treat disease, perform operations, and protect the public health in general. In fact, there should be no examination on methods of treatment, but the examinations should be on such fundamental branches as physiology, anatomy, chemistry, and pathology; that a knowledge of disease be possible in order that it may be diagnosed, especially the contagious and infectious diseases, for the protection of the public health. This knowledge would harm no one, even if he practiced Christian Science.'"

THE CITY HOSPITAL OF PROVIDENCE, RHODE ISLAND

The Providence City Hospital is the subject of the first editorial in the April issue of the Rhode Island Medical Journal, written under the title "Our Civic Pride." The editorial says:

"The Providence City Hospital has been in existence but little more than twenty years. During that time this hospital has made such prodigious advances in the care and treatment of the sick that it exerts a world-wide influence. Many of us, particularly in Rhode Island, may not appreciate that fact.

"In addition to the visitors who come to observe, there is a larger group who come to study, for this hospital has always encouraged study. Rockefeller Foundation lends doctors and nurses to the Providence City Hospital for training. The Harvard School of Public Health also sends its students here once each year for observation, and Tufts Medical College sends two students per month for study and training. In addition twenty hospitals have affiliations whereby they are able to send their nurses through the hospital's training school for nurses.

"Only a portion of the hospital's work lies in teaching. Every week brings one or more letters from various parts of the world to the superintendent requesting advice for or criticism of plans for hospitals, administration and other matters pertaining to hospital work. Last week one came from Sao Paulo, Brazil. All these questions are answered with care. Other cities at times have called the superintendent to survey their health problems and to suggest corrective measures. This happened with two of the largest cities in America; with a man of this high executive capacity that has become nationally and interna-

We believe you will find of interest the chart reproduced below, including summary of findings in typical case of pernicious anemia treated with Ventriculin . . . Booklet on Pernicious Anemia will be sent promptly on request.

PARKE, DAVIS & CO.

Detroit, Mich. - Walkerville, Ont.

DIAGNOSIS. Pernicious anemia.

INITIAL BLOOD COUNT: Red blood cells 1.5 million per cu. mm.; Hemoglobin (Newcomer) 21 per cent; Reticulocytes 1.0 per cent.

TREATMENT. Ventriculin 30 Gm. daily.

PHASE OF REMISSION. On sixth day of treatment: RBC 2.0 million; Hemoglobin (Newcomer) 30 per cent; Reticulocytes 32.0 per cent (calculated rise for 1.5 million red blood cells at beginning of treatment = 22.3 per cent, exceeding expected rise by 9.7 per cent).

PROGRESS REPORT. On the twelfth day after Ventriculin was begun the following blood count was recorded: RBC 2.9 million; Hemoglobin 52 per cent; Reticulocytes 0.4 per cent. (Expected weekly increase = 500,000 red blood cells per cu. mm. Actual increase in this patient = 700,000 red blood cells per cu. mm.).

tionally known and recognized, the Providence City Hospital has had one great advantage from its inception. In correlation to this it has also had as directors men of rare ability. Had it not been for these men Providence would very likely have had just another hospital, that is, brick and plaster. The methods, first put into practice here, are now studied and copied all over the world. The influence on world health which this hospital will have is inestimable."

The City Hospital has about 230 beds, devoted to nearly every form of practice, including contagious diseases. The source of the pre-eminence of the hospital is the superintendent, Dr. D. L. Richardson, who not only keeps himself informed daily regarding every case, but is also the intimate friend of every member of the Medical Staff.

ANNUAL MEETINGS IN SOUTH CAROLINA

While the Medical Society of the State of New York has evolved the plan of publishing the annual reports of its officers and committees before its annual meeting, many other States defer theirs until the meeting of the House of Delegates. South Carolina has taken a step forward, as is shown by the following item in the April Journal of the South Carolina Medical Association:

"On the night of Tuesday, May 5, the House of Delegates will convene at the Poinsett Hotel. The routine work of the House consists chiefly in hearing reports of the various committees appointed by the President and action on the same. An innovation was introduced last year to attempt to shorten the sitting of the House in order that the members might have more time for rest and recreation by having the councilors submit their individual reports to the Council itself and any matters of importance so submitted be incorporated in the general report to the House by the Chairman of the Council. Again, the reports of the various committees where possible were submitted in writing to the members of the House before their arrival and the chairmen of the respective committees requested to briefly summarize the original reports before the House. This plan, if carried out again, should reduce the time of the session of the House of Delegates to about three hours instead of four, five or six as in previous years. The outlook at the present time seems to indicate that there will be no prolonged discussions over constitutional amendments or other radical changes in the usual routine of the House. The election of officers will necessarily call for the keenest interest of the entire Association and properly so. Very careful thought should always be given to this important matter. Comparatively few changes along

Definite dosage
Ease of administration
Sensible economy

Each pill contains 0.1 gram (1½ grains) of physiologically tested digitalis leaves. The finished pills, too, are biologically assayed, thus giving re-assurance of their activity.

Each pill represents 15 minims of the U.S.P. tincture and permits of more accurate dosage than do liquids, as drops may vary in size.

These pills contain digitalis in its completeness and not any separated or extracted part of it, therefore present the entire therapy of this valuable drug.

Physician's trial size package and literature sent free upon request.

this line may be expected as this is somewhat of an off year and the offices to be filled are not numerous. The meeting of the House of Delegates, therefore, bids fair to be efficient and harmonious."

PROGRAM OF ANNUAL MEETING IN OHIO

Since the Medical Society of the State of New York is preparing and publishing its plans for its annual meeting on June 1-3, 1931, in Syracuse, it will be interesting to note the publicity given to the Ohio Annual Meeting to be held in Toledo, May 12 and 13, 1931, as set forth in the April issue of the *Ohio Medical Journal*.

The official meeting will be preceded by a clinic day, to be held Monday, May 11, under the auspices of a committee of the Toledo Academy of Medicine and the Lucas County Medical Society. The morning will be devoted to clinics in the hospitals of Toledo, while the afternoon program will consist of a single meeting in the building of the Academy of Medicine.

A golf tournament will also be held on Monday in the Inverness Country Club, Toledo, with a banquet in the evening.

The official sessions will open on Tuesday morning, May 12, with a general session held in combination with the House of Delegates. A second session of the House of Delegates will be held on Wednesday afternoon.

The second general session will be held in the evening of Tuesday, and the program will consist of addresses by the President and the President elect, and a reception.

A third general session will begin on Wednesday afternoon at 1:30 with motion pictures furnished by the Petroalgar Laboratories, which are described as follows:

"1. EXPERIMENTAL GASTROENTEROSTOMY: Prepared at Northwestern University by Drs. W. F. Windle and H. B. Kellogg, showing posterior gastroenterostomy performed aseptically on a number of monkeys and dogs, with later photographic studies following the recovery period, with graphic illustration of significant phenomena.

"2. REPAIR OF URETHROCELE, CYSTOCELE AND LACERATIONS OF THE CERVIX: Prepared at St. Luke's Hospital, Chicago, by Dr. Harold O. Jones, Associate Professor of Gynecology, Northwestern University. The introductory discussion outlines the etiologic factors of these lesions and gives the indications for repair with complete description accompanying the operative procedure, demonstration of the pathology, dissection, tissue repair and results.

Which form of S.M.A. should be used . . . ?

The Powder and Concentrated Liquid Forms of S.M.A. have the same composition when diluted according to directions, and give equally good results in practice. Infants may be changed from one form to the other whenever conditions arise which make the other form more convenient.

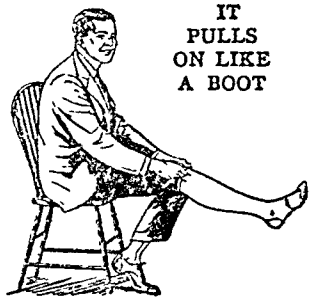
Powder Form

Powder Form . . This form lends itself to the preparation of a small quantity at a time as in starting feedings, or in giving supplementary feedings. It is also convenient for preparing individual feedings where cooling facilities are not available, or for use in traveling.

Concentrated Liquid Form*

Concentrated Liquid Form* . . This is the more simple form to prepare as it is already in liquid form. It is as simple as mixing two glasses of water. One container makes a liquid quart of S.M.A. ready to feed and should be used in cases where the infant is taking that amount of food in from one to two days. This form is very convenient in institutions where a large number of infants are being fed S. M. A. at one time. *Now available on the West Coast.

Protein S.M.A. (Acidulated)



Protein S. M. A. (Acidulated) is indicated in cases of diarrhea, malnutrition, marasmus, premature infants and other infants needing a higher protein intake. It is very effective also during the course of mild infections such as pyelitis and otitis media.

Write us for samples and ask for our little tabulated information booklet No. 35, no obligation, of course.

HAY FEVER

An Advertising Statement

HAY FEVER, as it occurs throughout the United States, is actually *perennial* rather than *seasonal*, in character.

Because in the Southwest—Bermuda grass, for instance, continues to flower until December when the mountain cedar, of many victims, starts to shed its pollen in Northern Texas and so continues into February. At that time, elsewhere in the South, the oak, birch, pecan, hickory and other trees begin to contribute their respective quotas of atmospheric pollen.

But, nevertheless, hay fever in the Northern States at least, is in fact seasonal in character and of three types, viz.:

TREE HAY FEVER—*March, April and May*
GRASS HAY FEVER—*May, June and July*
WEED HAY FEVER — *August to Frost*

And this last, the late summer type, is usually the most serious and difficult to treat as partly due to the greater diversity of late summer pollens as regionally dispersed.

With the above before us, as to the several types of regional and seasonal hay fever, it is important to emphasize that Arlco-Pollen Extracts *for diagnosis and treatment* cover adequately and accurately all sections and all seasons—North, East, South and West.

FOR DIAGNOSIS *each pollen is supplied in individual extract only.*
FOR TREATMENT *each pollen is supplied in individual treatment set.*

ALSO FOR TREATMENT we have a few logically conceived and scientifically justified mixtures of biologically related and simultaneously pollinating plants. Hence, in these mixtures the several pollens are mutually helpful in building the desired group tolerance.

must keep them well. The rates are less than cost, and are based on the ability of the person to pay, as hospitalization is coming to be looked upon somewhat as a public function.

"This service is open to groups such as teachers, employees of different business houses or corporations, unions, or any logical group applying for the same where ten or more apply, at five per cent higher charge or rate than the above schedule. It is also open to individuals, but the county reserves the right during the first year to refuse hospital service for operations and treatment for very apparent chronic ailments existing at the time the individual applies. It would not be fair to the county for $1 per month to take on an individual sick person who immediately needs a very expensive operation or treatment."

The Journal comments as follows:

"The state constitution gives the county units the right to maintain county hospitals and to support the same through public funds, but it is also our impression that it is provided that such facilities shall be extended only to indigent citizens. It will be interesting to watch the outcome of the experiment in Santa Barbara County in this—what might be called an initial experiment in state medicine in California. It is true that at the present time the experiment is only a small beginning, but the legal and other principles involved are not small."

The Santa Barbara County Medical Society on January 12th took the following action:

"It was then moved, seconded and unanimously carried, that the following motion adopted by the Public Relations Committee be adopted by the Santa Barbara County Medical Society and be incorporated in the minutes of this meeting:

"1. That no member of the Santa Barbara County Medical Society enter into any such agreement with the Santa Barbara County Board of Supervisors for professional services, as proposed in the enclosed plan, without the approval of the society.

"2. That no member of the Santa Barbara County Medical Society enter into any agreement with any organization or like group for professional services without the expressed approval of the society.

"3. That any member acting contrary to these recommendations be automatically suspended from the county society."

PHYSICIANS IN TELEPHONE DIRECTORY IN TEXAS

How to list physicians in a telephone directory was the subject of debate in the Harris County Medical Society according to the following report in the February number of the Texas State Journal of Medicine:

(*Continued on page 609—adv. xxvii*)

"Harris County Medical Society met on November 26, with 36 members present. Dr. M. J. Taylor, president, presided. Dr. Ray K. Daily, chairman of the board of censors, gave the recommendations of the board concerning the classification of physicians in the Houston Telephone Directory. The board of censors presented alternative recommendations for consideration:

"(1) That advertising be left entirely to the quacks; that all members of the Society be classified under physicians and surgeons, all names to be printed with the same type.

"(2) That the classification of specialties as used in the Directory of the American Medical Association be used in the telephone directory. In the even that the latter recommendation was adopted, that each specialist file a notice of his specialty with the board of censors and confine his practice to this special field; and, further, that all names classified under the various specialties shall be printed in the same type.

"The telephone company had recommended that a line, 'Member of Harris County Medical Society' be listed after the names of members of the society. The board felt that this would merely serve to increase the telephone bill and form another entering wedge of advertising.

"Dr. J. M. O'Farrell, in discussing the report, recommended that no other classification of specialties be used than those given in the Directory of the American Medical Association. He urged the adoption of the recommendation that members of the Harris County Medical Society not subscribe to the classification as now appearing in the Houston telephone directory.

Dr. J. E. Hodges said that he believed the classification was of no value and not in good taste. The regular classification under physicians and surgeons was not objectionable.

Dr. O'Farrell suggested that no member of the society be permitted to use bold face type listings.

Dr. B. T. Vanzant stated that he had no objection to the classified directory provided that the classifications given in the Directory of the American Medical Association are used. He suggested that a standard list of specialties be prepared, and that the specialties listed appear in accordance with a classification of specialties approved by the society.

"Dr. Ray K. Daily, in discussing the use of a classification of specialties, felt that a physician should either adhere to the general classification of physicians and surgeons, or it should be required that those classified under specialties adhere strictly to the practice of that specialty.

COSTS OF PUBLIC HEALTH IN OHIO

The April number of the *Ohio Medical Journal* contains a practical editorial on the costs of public health service, which says:

"The present costs of official public health work in Ohio generally are not excessive. While some may contend that a few of the functions now being undertaken by public health departments might be dispensed with without much detriment to the public, some communities are failing to adequately finance the work of their health departments.

"So, the big question confronting those directing the public health activities of the state and local communities is to prove they have been supplying the type of service which justifies the amount of money now being expended and deserves a more generous helping from the public coffers

"Public health work is a business undertaking, and like all business projects, must be based on a well-defined program and on sound economy. An effort must be made to produce the maximum of service with the funds available. Some health departments are finding themselves hard-pressed to convince the public in these times of business depression that they deserve an increased budget.

"The point which those directing public health activities in Ohio must recognize and keep in mind at the present time is well defined in the following editorial comment made in *Health,* official publication of the Dayton Department of Health:

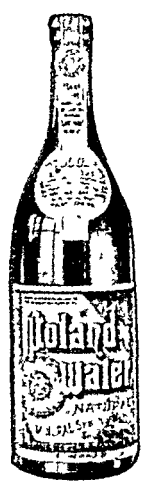
" 'There are certain health promotion functions the individual cannot do for himself. For children especially it is the State's first duty to see that these matters are done and done well. One writer has said: "The tragedy of this earth is a diseased child."

" 'There are other health functions which the individual should perform for himself. In this second class the State still has the duty to lead, to direct, to impart information and to stand by and give actual financial aid in cases of real indigency, emergency, etc. But for the State to do for the individual what he should do for himself puts an unnecessary burden upon the taxpayers.

" 'Many who are interested in public health in later years have failed to discriminate between these two functions. . . . . The functions of public health activities, whereby individuals are given information and assistance to do for themselves, should have special attention. If those who are interested in public health promotion do not properly plan for economy in expenditures, the toy balloons, attached to which many dreamers are now floating around in the air, are soon to be punctured by the hard-headed taxpayer. It is a splendid time to plan for thrift in public health work as in all other lines.' "

The following editorial from the March *Illinois Medical Journal* suggests that the most effective public health work is that given by practicing doctors without cost to the taxpayers:

"Statistics revealing the average reduction of the death rate in the U. S. registration area by more than 36 per cent in the last thirty years would seem to convince the most presumptuous body of lay investigators that the medical profession really does attend to its business in relation to the moot question of prophylaxis and public education.



"Some ailments of the human race have experienced an even higher percentage of reduction than that. While the national death rate has been cut nearly two-thirds, there are mortality figures from some causes that show that some scourges have been practically wiped out. This results of course from scientific prophylaxis based upon scientific research and scientifically administered. Lay-dictated legislation had nothing to do with it, nor did any so-called relief measures based upon false ideas of the good arising from that socialized menace—state medicine."

THE USE OF TRICHOPHYTIN AS A DIAGNOSTIC AND THERAPEUTIC AGENT IN MYCOTIC INFECTIONS OF THE SKIN

By LAIRD S. VAN DYCK, M.D., JEROME KINGSBURY, M.D., BINFORD THRONE, M.D., and C. N. MYERS, Ph.D., NEW YORK, N. Y.

From the New York Skin & Cancer Hospital

THE object of this study has been to find a simple method for the diagnosis and treatment of Trichophyton and Epidermophyton infections of the skin which would be available to all physicians who have to deal with these extremely prevalent conditions. The search for the organisms in scrapings and smears from the lesions and the time which is necessary for their growth on artificial culture media prove to be fruitless in many cases even with the aid of expert mycologists.

Attempts have been made by other investigators to show the specificity of individual fungi through intradermal and complement fixation tests, but this has not led to any sureness in their differentiation. Scholtz's[1] experiments showed that the allergic reactions with trichophytin from different strains of trichophyton fungi were the same. Consequently, they must be considered as group reactions. Scholtz[1] believes that on account of the great variability which the fungi show on very inconsequential changes in the culture media, the identification of the fungus is not yet sufficiently established, and from a clinical point of view is of little value. Whether this be true or not, microscopic and cultural studies should be made in all cases where the facilities are at hand and time permits.

For the past six months in our clinic, an intradermal trichophytin test has been done routinely in all cases diagnosed clinically as Tinea, including intertriginous, vesico-pustular and dyshidrosiform eruptions. The trichophytin used is a polyvalent extract of various species of trichophyton, including T. gypseum, T. cerebriforme, T. migroides, T. rosaceum, T. violaceum, and T. crateriforme. It was prepared in accordance with the method of Scholtz.[1]

The test used consists in an intradermal injection of 0.1 c.c. of a 1:10 dilution into the flexor surface of the forearm. A positive reaction is denoted after 24 hours by the appearance of an area of redness and infiltration at the site of injection. On the surface of this infiltrated area, there may be one or more vesicles surrounded by a red flare which may cover the entire surface of the forearm.

If there was no change in the skin at the site of injection after 24 hours, or if there was only a small area of redness without definite infiltration, it was considered a negative test.

The intradermal test was used rather than scratch or patch tests, on account of more accurate dosage, more uniform absorption, and the shorter time necessary to elicit a positive or negative reaction. Sulzberger and Lewis,[2] using contact tests, found that it was sometimes necessary to wait two weeks for a positive reaction. The injections were always given in the flexor surface for the following reasons; first, this region is easily accessible, and secondly, Ernst Friedrich Mueller[3] has shown that the greatest response of the vegetative system is elicited when intradermal injections are given here or in the skin on the extensor surface of the thighs. The injections are not given in the affected area as is done in sycosis vulgaris. In this condition, a general allergy exists while in sycosis as Cranston Low[4] says, there is a local cellular sensitization.

The severity of the reaction to a trichophytin test seems to depend on the degree of allergy which exists in each particular patient, and is often not in proportion to the clinical severity of the condition for which the patient had applied for treatment.

Reactions were roughly classified according to their severity as negative, one plus, two plus, three plus, and four plus. Only those

were considered positive which showed an elevated, infiltrated lesion at the site of injection, and those which showed a vesicle resulting in central necrosis were considered four plus. This necrosis sometimes leaves a small superficial scar. In cases where the first test is negative, subsequent tests after an interval of several days will often appear to be positive even in patients who have no visible sign of a mycotic infection. These "secondary" positives we believe to be of no clinical significance, but merely indicate that the original test has produced a local sensitization. This is similar to the experience of Lehner and Rajka,[5] who showed that it was possible to sensitize the skin by injections of trichophytin, tuberculin and luetin. They observed this sensitization develop first on the repeatedly used parts and in their immediate neighborhood, in one case after the fourth, and in two after the fifth depot injection. First the used parts became sensitized, then the immediately adjacent parts, and later the distant parts of the skin. As the distant parts of the skin became sensitized, the repeatedly used parts and their adjacent parts gradually became desensitized, as evidenced by milder reactions to the injections.

During our observations of patients who had received intradermal trichophytin tests, it was noted incidentally that many who gave the most strongly positive reactions showed a marked improvement in their skin condition a few days after the test was made. This led to further observation on a series of one hundred cases in which positive reactions were obtained on the first test. In order to determine whether it was possible to desensitize these patients, subsequent injections of trichophytin were given intradermally every four or five days. We used a 1:10 dilution for the preliminary test, and then followed with a 1:50, 1:10, 1:5, 1:2, and 1:1 dilutions as soon as the preceding reaction became less marked. From one to three wheals were given at each treatment except the first. Only one wheal was used for the test.

It was noted that most mild cases of Tinea limited to the toes, gave a weakly positive reaction to trichophytin injected intradermally into the forearm, while the lesions themselves became very itchy. One such case also developed a mild attack of hay fever, and the itching of the toes became very acute. Wise and Sulzberger[6] have recently reported a case in which a skin test with trichophytin elicited not only a skin reaction, but an attack of violent sneezing and edema of the eyelids and nose, which were checked only by the administration of epinephrin. An urticarial wheal appeared at the site of injection a few minutes after the test was made in several cases of our series, but no violent reactions were observed. Ramirez[7] has reported a case of asthma due to Tinea.

Blood chemistry tests were done routinely in all of our cases. A hyperglycemia was usually found. The average blood sugar for the group was 105 mgms. per 100 c.c. of blood. The Hastings-MacLean method was used, our average normal being 90 to 100 mgms. per 100 c.c. The local treatment used during our study of these one hundred cases was nothing but boric acid ointment.

In this connection, it cannot help but be striking that these organisms can only be grown on a medium which contains sugar. Usher[8] has shown the sugar content of the sweat, and Urbach[9] has

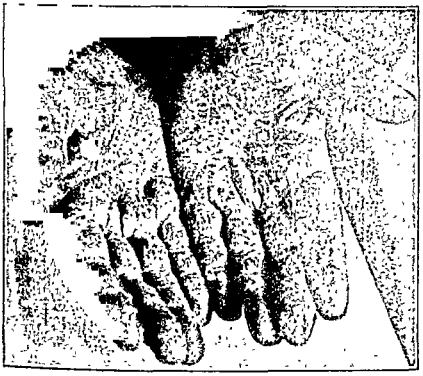
100	43	Tinea	Hands and feet		3 months	++	5	1 month	Improved



shown that the skin is a very important depot for the storage of sugar and that its sugar content is in direct ratio to that of the blood. This may have some influence in increasing susceptibility, and although we have not found that a restricted carbohydrate alone is curative, it does seem to be an important aid in the handling of these cases. As regards blood chlorides, urea nitrogen and uric acid, no marked deviation from the normal was observed.

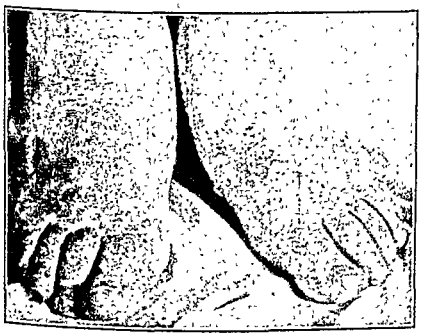
During this investigation, it was noted that recurrences or exacerbations were uniformly seen when the curative injections were not continued until there no longer appeared any reaction at the sites of injection; or in other words, until a general desensitization had been developed. We think this is extremely important.

Table II shows the results of thirty patients used as controls in the application of the trichophytin test. Clinically these patients were free

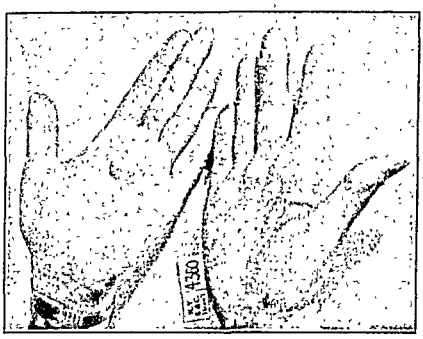
from mycotic symptoms. The trichophytin extract used in these experiments was freshly prepared and free from bacterial contamination.

In a series of patients suffering with Pityriasis Rosea the trichophytin test was *positive* in *all* cases. This will be reported in detail in a future paper.

FIGURES 1 AND 1A. PATIENT NO. 7



Tinea of the Hands and Feet, Vesico-pustular Type.



SUMMARY

One hundred cases of mycotic-like eruptions which gave a positive trichophytin test were treated with subsequent intradermal injections of trichophytin. The clinical results observed over a short period were as follows:

Apparently cured 32 per cent; greatly improved 28 per cent. Slightly improved 21 per cent; unimproved 19 per cent.

Sufficient time has not elapsed to allow any conclusions as to the duration of the immunity which this method of treatment may produce.

FIGURES 2 AND 2A. PATIENT NO. 24

Tinea, showing intertriginous lesions on the toes and dyshidrosiform eruption on the palms.

THE MANAGEMENT OF DIABETICS IN GENERAL PRACTICE*

By LEO F. SCHIFF, M.D., PLATTSBURG, N. Y.

THE discovery of insulin and the research connected with it, has vastly increased our knowledge of Diabetes Mellitus, and materially altered our conception of the disease and its treatment. We now know that the disease is a condition of lowered function of the cells of Langerhans in the pancreas resulting in deficient carbohydrate metabolism. The significance of glycosuria as a symptom and as an indication for control of treatment fails, for we may have diabetes without glycosuria and often encounter glycosuria that is not diabetic. It is upon the demonstration of hyperglycemia that the diagnosis rests; and estimations of blood sugar content are necessary from time to time to assist in regulating treatment. For those in contact with adequate laboratory facilities, this matter presents no particular difficulty, but for the practitioner in the isolated community, conditions are different. Deterioration often occurs rapidly in samples of blood sent to the laboratory for sugar estimation. Reliable results are obtained only when the test is performed soon after taking the specimen. It is, therefore, impractical to attempt to send blood to a laboratory situated at any distance. This fact together with the dietetic arithmetic involved, has deterred many from undertaking the treatment of diabetes in general practice, and led to the establishment of special diabetic clinics in many hospitals, and intense specialization along this line in the practice of medicine. Such conditions work out satisfactorily in larger communities with hospital facilities, but the diabetic is a diabetic all of the time whether he is at the hospital or at home, and this condition complicates all of the other ailments to which he may be subject and for which he may need to be treated by his family physician. Of course, there are certain phases of the disease which demand hospitalization if possible, but after the emergency is over the patient still needs the advice of a physician. It is not always easy to go a considerable distance and at considerable expense, for a consultation and check-up. It is, therefore, the obvious duty of the family physician to acquaint himself with the management of the disease, and where laboratory facilities are not readily available, to equip himself for sugar determination in his office. The extreme accuracy of a highly technical laboratory procedure is not necessary; a simple method with not too great a factor of variability will do very well. I have found the micro method of Epstein satisfactory.

The successful treatment of any condition involves an appreciation of the etiological factors, the pathology and significance of the various symptoms together with clinical and laboratory findings. The etiological factors behind the pancreatic dysfunction of diabetes are many, and it is not necessary to enter into a discussion of them here. It is well to recall, however, that this dysfunction may be due to cell changes of a temporary and remediable character, and that such cases of diabetes are really curable. In most instances there has been irreparable cell destruction, but added to this is usually a functional disturbance of the remaining cells of the pancreas from the overwork caused by the stimulation of a relatively high carbohydrate intake. I would particularly call attention to cases of diabetes in middle age and later, which are probably secondary to a general arteriosclerosis and are often progressive. A great many cases of so-called diabetic gangrene prove to be due to arteriosclerosis, and the diabetes is an associated condition. These patients require in addition to the treatment for diabetes, treatment for the arteriosclerosis.

Inasmuch as nature is most bountiful in providing us with capacity far beyond our average requirements, a moderate interference with the glycolytic function of the pancreas produces no apparent ill effects. It merely diminishes the capacity for carbohydrate utilization. When the interference is great enough to reduce the glycolytic function below the daily needs of the patient, clinical diabetes ensues. There is a rise in the blood sugar, at first only after the ingestion of food, later more or less constant. Then the kidney threshold for glucose is reached and glycosuria ensues. Eventually the body becomes unable to metabolize sufficient glucose for its daily needs and there results a marked disturbance in the metabolism with loss of weight and strength ending in ketosis. These latter manifestations together with the increased susceptibility of the glycemic patient to infection, constitute the graver aspects of the disease.

Before undertaking the treatment of a diabetic condition, one should endeavor to estimate approximately the extent of the glycolytic deficiency. If the body can still metabolize sufficient carbohydrate to maintain the patient's usual life without the danger of ketosis, it is necessary only to restrict the intake. But when sufficient carbohydrate cannot be utilized, a restriction of the intake, although it may cause the disappearance of glycosuria and of hyperglycemia, is not sufficient. The body will slowly starve, metabolic process gradually become perverted, and ketosis will ensue. It is, therefore, evident that the prime object of treatment in such a case is to see that the patient ingests *and metabolizes* (with the aid of insulin) sufficient carbohydrate to maintain himself without disturbing his acid-base balance. It is far wiser to err on the side of moderate over-

* Read before the Fourth District Branch of the Medical Society of the State of New York at Saratoga Springs, September 9, 1929.

feeding with resultant slight hyperglycemia and glycosuria and to be sure that sufficient insulin is taken to maintain proper metabolism. On the other hand, extremely high feeding and unnecessarily large amounts of insulin tend to produce increase of weight beyond the desirable.

Although glycosuria is no longer the criterion for a diagnosis of diabetes, it is still one of the earliest and most important symptoms in that it calls attention to the existence of the disease in the majority of cases. The sugar may be found in the routine examination of the urine of a patient in whom a diagnosis of diabetes was not suspected; or there may be other symptoms suggesting the diagnosis, as weakness, loss of weight, excessive thirst or appetite, polyuria, eczema particularly about the genitals, furunculosis or gangrene. The absence of sugar in the urine of a patient presenting any of these symptoms will not rule out diabetes and a blood test will be necessary. Whenever sugar is found in the urine it should also be tested for diacetic acid, with Ferric Chloride, being careful not to be deceived by the purple reaction following the ingestion of aspirin and allied drugs.

CHART I

LOW CARBOHYDRATE TEST DIET

Breakfast
1 egg
1 cracker
Tea or coffee

Lunch
1 cup clear broth
1 dish (3 oz.) green vegetables, raw or cooked
1 cracker

Dinner
1 egg
1 dish vegetables, as before
1 cracker
1 cup of tea, coffee, or broth
Use saccharin if desired to sweeten tea or coffee.
Use cream in preference to milk.

Vegetables to be taken from list below. They may be eaten raw with a little oil and vinegar, or cooked in water without any flour thickening.

Egg may be prepared in any manner desired.

A reasonable amount of butter may be used on the cracker.

The above diet contains approximately 22 grams of carbohydrate, 15 grams of proteid, and 15+ grams of fat, with a calorie value of approximately 300.

Lettuce	Dandelions	Cauliflower
Cucumbers	Swiss Chard	Egg Plant
Spinach	Celery	Cabbage
Asparagus	Mushrooms	Radishes
Rhubarb	Tomatoes	Leeks
Endive	Brussels Sprouts	String Beans, canned
Marrow	Water Cress	Broccoli
Sorrel	Sea Kale	Artichokes
Sauerkraut	Okra	
Beet Greens		

Glycosuria may be due to:

1. Excessive ingestion of carbohydrate beyond the capacity of a normal pancreas (alimentary glycosuria).

2. Deficient glycolysis (diabetes mellitus).

Both of these conditions will be accompanied by hyperglycemia.

3. Persistent excretion of sugar by the kidneys without hyperglycemia (renal glycosuria).

If the patient presents no grave symptoms and there is no more than a trace of diacetic acid in the urine, he may be given an extremely low carbohydrate diet (Chart I) for from three to five days and directed to return for further examination. His weight should be recorded. The appointment for the next examination should be at a time when a satisfactory specimen for blood examination can be taken; that is, either before breakfast or at least three hours after the meal, and the patient should bring with him a mixed specimen of urine of that morning and the night before. In most cases this will be as satisfactory as a full twenty-four hour specimen. The examination of the blood and of the specimen of urine will throw a great deal of light on the patient's condition. There are four possible combinations of results.

1. Urine free of sugar, blood approximately normal. In this case the patient should be placed on a diet sufficient to maintain energy. Roughly such a diet may be constructed by allowing 2/3 gram of carbohydrate for each pound of body weight (a little less than this if the patient is obviously overweight) and using the dietary score card (Chart II) which accounts only for carbohydrate ingested as such, and disregards the available carbohydrate in proteid and fat. Ordinarily a patient will not take an excessive amount of proteid and fat in combination, but if he is not satisfied with his diet or there is any reason to suspect that he is taking too large a proportion of proteid and fat, it is well to construct a diet list for him. There are many excellent tables readily available to assist in making out such a list. The condition of the blood and urine, and the patient's weight and general condition, determine the further regulation. Loss of weight calls for an increase in diet. A rise in blood sugar beyond 150 calls either for a decrease in the diet or the administration of insulin.

2. Urine free of sugar and the blood sugar over 150. Such a case should be considered as at least of moderate severity, the diet raised to maintenance standard and insulin administered. It is well in beginning the administration of insulin, in the absence of complications, to divide the diet so at least 40% of the carbohydrate is taken at what is usually the patient's largest meal and to give 10 units of insulin at that time. Further tests may indicate the necessity for increasing the amount of insulin. If over 10 units are needed, it is well to give at least two doses. In following the progress of a patient under this treatment it may be advisable to arrange for blood sugar tests at different times of the day so

CHART II

DIABETIC SCORE SHEET

(Each point equals approximately 1 gram of carbohydrate)

Your score is:

Breakfast .....
Dinner .....
Supper .....

1 cracker counts	5
1 tablespoonful cereal, dry	10
1 shredded wheat biscuit	20
1 medium orange or apple	10
½ medium grapefruit	10
1 dish green vegetables	5
1 dish root vegetables	10
1 glass of milk	10
½ slice of bread, ½" thick	12

Add to this, eggs, meat, fish, cheese, butter, cream (no milk), tea, coffee, broth, gelatin with fruit juice flavor and saccharin.

Do not use flour gravies or cracker crumbs to fry in (unless you count the cracker in your score) No liver or sausage.

Use saccharin to sweeten.

as to get the blood sugar level before and three hours after the administration of insulin.

3. Sugar present in urine and the blood sugar low. In this instance we have a case of renal glycosuria. The patient should be put on a maintenance diet and the test repeated after a reasonable interval, to see whether a true diabetes may exist with the renal glycosuria, a condition which often occurs. If on the second visit there is still no evidence of diabetes, the diet may be raised and a third test taken after another interval.

4. Sugar present in the urine and high in the blood. The procedure is the same as in Paragraph 2.

If at the first examination the patient shows in addition to sugar, a considerable amount of diacetic acid, it is advisable to take a blood test at once and proceed with the administration of insulin, giving more carbohydrate than necessary at first in order to minimize the danger of insulin shock and the discouragement of the patient at the outset. In cases presenting the more severe aspects of the disease or complications, immediate hospitalization is preferable, but if not practicable the patient must be given a reasonably liberal carbohydrate diet and insulin. Frequent blood tests will give the indications for changes in the diet and medication, but so long as there is any evidence of acidosis, it calls for more insulin, and this in turn for more carbohydrate if the blood sugar is low. In the absence of facilities for blood sugar tests it is safer to ply the patient liberally with carbohydrate and control insulin administration by testing the urine. As long as diacetic acid is present it calls for more insulin, and this in turn for more carbohydrate, sufficient to maintain a trace of sugar in the urine.

In all these cases, better results may be secured if one takes the time to explain to the patient the reason for doing the various things. Booklets for patients' use on this subject have been published within the last few years. In the regular management of a case, one must wait a sufficient time after making any change in diet or insulin before attempting to evaluate the results.

THE PROSTATE GLAND FROM THE VIEWPOINT OF THE INTERNIST

By JOSEPH R. WISEMAN, M.D., SYRACUSE, N. Y.

MOST of the literature on the prostate gland has come from the pen of the surgeon or the urologist. An appraisal of this important organ through the eyes of the internist has seldom been attempted. In 1915[1] I published some observations along this line of thought, and for many years have made a systematic examination of the prostate gland an integral part of the routine investigation of each male patient.

The prostate gland is both a urinary and a sexual organ. About the size of a horse-chestnut it is situated at the neck of the bladder and is penetrated by the prostatic portion of the urethra. From the capsule strands of muscular and connective tissue radiate internally to form the supporting structure of the tiny but important prostatic glands, the secreting structure of the organ. These glands resemble minute bunches of grapes whose fine ducts join with each other and finally empty by 15 or 20 openings on the floor of the prostatic urethra along the sides of the veru montanum. "The two ejaculatory ducts pass through the substance of the prostate and empty upon the summit of the veru montanum, a small but important muscular structure which forms part of the floor of the prostatic urethra.

"The prostate gland is provided with a free blood supply, and is surrounded by a plexus of veins so large and so closely interwoven as to suggest the cavernous spaces of an erectile tissue. The veins of the prostate form one of the connecting links between the portal and inferior caval systems. The nerve supply shows an extraordinary wealth of nerve fibers, ganglion cells, and nerve end-organs. It is conceivable that the unusually rich blood and nerve supply of the prostate may determine on the one hand the readiness with which the gland undergoes congestive changes, and on the other hand the numerous local and general nervous manifestations associated with prostatic inflammation.

"After studying the structure of the normal prostate it becomes easy to understand some of the changes which chronic inflammation brings about. If, for example, there is an increase of the connective tissue sufficient to compress some of the numerous tiny ducts the secretion of the tubular glands becomes dammed back, dilatation of the glands follows, and often small cysts are formed. The inflammatory changes may involve principally the stroma which increases in density, thereby producing a hard prostate, or the glandular structures may bear the brunt of the inflammatory changes and become distended with purulent secretion. In the latter instance an enlarged but soft or adenomatous prostate results. As a rule, both the glands and the interstitial tissue are involved, although often in unequal degree. Cases of long standing with much sclerosis show contraction or even obliteration of many glands."[1]

Chronic prostatitis is the most common disorder of this organ. How does infection take place? In acute gonorrhea the organisms make their way into the prostate directly from the urethra in an immense majority of patients. The gonococcus, however, usually dies out relatively soon, and is seldom demonstrated in the prostatic secretion after the lapse of 3 years. How are we to account for the numerous cases of chronic prostatitis showing evidence of infection for much longer periods of time? How can we explain the not inconsiderable proportion of cases of prostatitis in which the existence of a previous urethritis can clearly be excluded? The present day tendency is to regard blood stream infection from near or distant foci as the probable answer to these questions. Wolbarst[2] and Wohlstein[3] have called attention to the existence of a previous low grade nonvenereal prostatitis in cases of acute anterior gonorrhea which had as yet shown no evidence of posterior involvement. In 100 such cases of acute anterior gonorrhea (first infections) Wolbarst found evidence of previous prostatitis in 30 per cent. In nonvenereal prostatitis the infecting organisms probably come from common foci such as teeth, tonsils, gall-bladder or rectum. They may involve the prostate after various acute diseases. It has long been believed that such sexual practices as coitus interruptus, excessive masturbation or intercourse, and prolonged sexual excitement without gratification lead to a chronic congestion of the prostate which paves the way for infection to take place. Pelouze[4] states that an enormous percentage of males presenting infected teeth and tonsils also have infected prostates and considers the male focal infective triad to be teeth, tonsils and prostate gland. He believes that general lowered resistance is an important factor and that in many instances we are dealing with an individual, who among other difficulties has an infected prostate gland. Pelouze[4] cites the case of a man who because of slight nocturnal frequency of urination presented himself for prostatic study 6 times within a year. Each time the prostatic secretion had been absolutely normal. Some weeks later he had an acute inflammation of one tonsil. Six weeks after this event his prostatic secretion contained countless large clumps of pus while the gland had become acutely tender and decidedly enlarged.

Wildbolz[5] considers hematogenous or metastatic prostatitis a common disease. He cites the occurrence of metastatic involvement of the prostate in general infections such as pyemia, miliary tuberculosis, pneumonia, etc. He observed 36 patients with normal urinary passages in whom a metastatic prostatitis followed influenza, a slight sore throat, a gastrointestinal disturbance or showed no evidence of the original cause. Since the prostate gland furnishes a favorable site for the localization of organisms, he believes it possible that in patients in whom a few organisms circulate in the blood stream without causing symptoms, they may settle in the prostate and produce a latent prostatitis. Young,[6] however, feels that the hematogenous origin of prostatitis is not proven.

VonLackum[7] believes that 40 per cent of prostatitis is of hematogenous origin. A comparative bacteriological study of various foci of infection in the absence of any history of previous urethritis, has often shown the same strain of streptococci in periapical tooth lesions, tonsils and prostate. In 405 cases, carefully made cultures of the prostatitic secretion gave the following results; streptococcus 36 per cent, staphylococcus 22 per cent, sterile 35 per cent. Of 1,667 cases of chronic prostatitis a history of gonorrhea was obtained in 74 per cent. Young[8] found a history of gonorrhea in 73 per cent of 358 cases. VonLackum[7] cites three probable mechanisms by which the infected prostate produces general symptoms;—the infection or the focal toxins may be conveyed from the prostate by the blood stream, or the symptoms may be reflex. Among the clinical entities which he believes have been proven to be of prostatic origin he mentions arthritis, neuritis, myalgias, ocular infections, secondary anemia, several types of skin disorders, backache, abdominal pain and functional gastric complaints. He adds, however, that the focal role and scope of the prostate have not been fully determined.

The symptoms produced by chronic prostatitis are exceedingly varied. Urination may be frequent, painful or urgent. Premature ejaculations, diminished libido, imperfect erections or frequent nocturnal emissions may be present. Psychic symptoms are common with depression, insomnia, irritability and a psychoneurotic state. Referred symptoms, usually of a painful nature, are probably the most important and as Young[9] states may involve any of the regions from the diaphragm to the toes. Low back pain in the male should always direct attention to the prostate

gland. The pain may be abdominal, simulating gastrointestinal disorders, or may have the distribution of renal colic. It may affect the perineum, hips or thighs. In my experience as an internist most of the cases of chronic prostatitis have been without symptoms referable to the prostate. The affection of the gland was inadverdently discovered during the course of a general examination. In some of the patients, however, considerable relief was afforded by treatment of the prostatic condition both in those individuals presenting prostatic symptoms and in the silent cases where none were present.

The recognition of the condition of the prostate depends chiefly upon rectal touch accompanied by massage, and upon the examination of the expressed prostatic secretion. Additional information may be obtained by the urologist from the direct inspection of the prostatic urethra. The finger in the rectum may find the gland enlarged, indurated, nodular, boggy, or tender, possibly with adhesions which limit its mobility. The seminal vesicles which are situated directly above the prostate are so closely connected to it that often they cannot be distinguished as separate structures. The carcinomatus gland is usually of stony hardness and may be nodular. Tuberculous changes may be difficult to distinguish from those of chronic inflammation, but the occurrence of tuberculous disease in the epididymis or elsewhere and a suggestive history or clinical course are helpful points. Prostatic hypertrophy occurs after middle life and presents a firm elastic gland, uniformily enlarged.

Prostatic massage should be performed when the patient has a fairly full bladder, so that he may void soon afterwards and wash out the expressed secretion. The gland should be methodically stroked with the index finger from above downwards with final stroking along the course of the membranous urethra to clear out the secretion as fully as possible. The exploration should be thorough and cover all parts of the gland as only in this way can accurate knowledge of its condition be obtained. Gentleness, however, is essential. The appearance of the prostatic secretion should be noted and a drop placed upon a glass slide for direct examination. If secretion does not appear at the meatus, stroking along the perineum and urethra will usually bring it out. If no secretion whatever can be obtained the urine voided after massage should be centrifuged, and the number of pus cells present compared with another specimen of urine passed at a subsequent time. This method, however, is less satisfactory than direct examination of the secretion.

Normal prostatic secretion, which usually includes that from the seminal vesicles and vasa deferentia, is a thin milky fluid containing numerous lecithin bodies (round refractile structures the size of a red blood cell) and a few leucocytes, not more than 2 to 6 per high dry field. The appearance of pus cells in greater numbers indicates inflammation of the gland. Pus cells in clumps are pathognomonic of infection. Even though prostatitis be present pus may not appear the first time the gland is examined. It may require 2 or more massages before pus is finally obtained from an infected gland. In some instances the prostate may feel entirely normal per rectum, yet large numbers of pus cells are found in the expressed secretion. The entire diagnostic procedure can be done very quickly and the microscopic examination of the fresh secretion can be completed in a moment or two. I am convinced of the great value of the combined procedure of palpation of the prostate gland by massage together with the microscopic examination of the prostatic secretion, in order that an appraisal of the condition of this organ may be obtained. Hugh Young[8] states that if this procedure were routinely followed in physical examinations, "many a poor individual who has continued to suffer while stigmatized a neurasthenic would find relief, many a case of supposed rheumatism, sciatica, lumbago, and renal colic would be correctly diagnosed and cured."

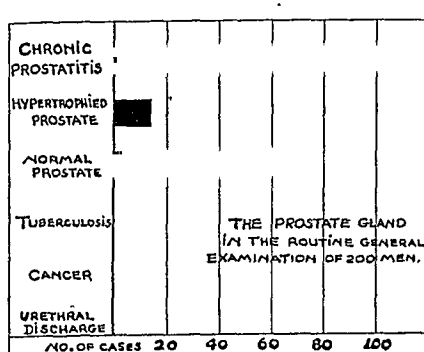

Chart No. 1

I have examined my office records of the last 200 males who received a routine general examination. They consulted me because of a wide variety of general symptoms, few of which were related to the genito-urinary tract. They formed quite a different cross section of medical practice than would 200 males seen in the office of a urologist. One hundred and eight cases, 54 per cent, showed evidence of chronic prostatitis. Fourteen cases, 7 per cent, had hypertrophied prostates. Seventy-eight were considered normal. Neither carcinoma nor tuberculosis was noted in this group. The total number of cases in the

series showing disease of the prostate, either inflammation or hypertrophy, was therefore 122 or 61 per cent, a strikingly large group which fully justifies the use of the diagnostic measures above described. Although the number of cases is not great, it seems of sufficient size to indicate a definite trend. It must further be noted that in not a single patient was any urethral discharge present. Other authors have variously estimated that from 35 to 90 per cent of all adult males have infected prostates. Wear[10] quotes Von-Lackum to the effect that in a review of 2,000 cases, 35 per cent showed some degree of prostatitis.

The age distribution (chart 2) of the prostatic cases shows a proportionate increase after the age of 50. The youngest patient was a strapping big lad of 17, referred by an ophthalmologist because of a hemorrhage into the vitreous of one eye thought to be due to tuberculosis of a blood vessel. The prostate gland was definitely wid-

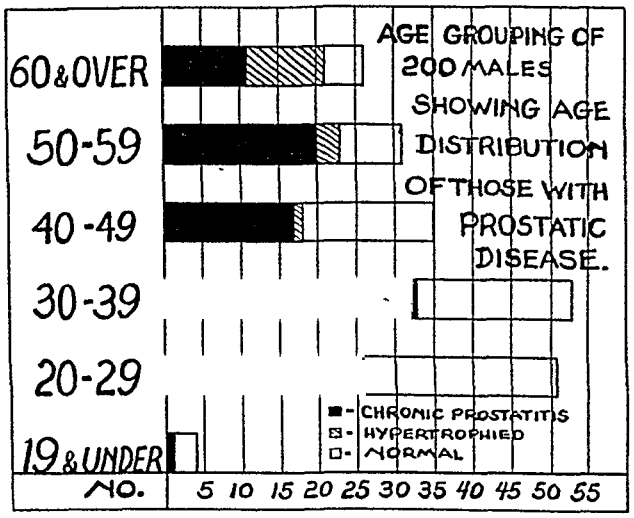

Chart No. 2

ened and somewhat indurated with 30 pus cells per high dry field in the prostatic secretion.

Chart 3 shows the most frequent collateral diagnoses in 108 males with chronic prostatitis. Two or more conditions often occurred in the same patient. The high incidence of chronic tonsillitis, 42 cases, is noteworthy.

I shall only touch upon the treatment of chronic prostatitis. The time-honored method of prostatic massage still holds first rank as the most effective method available. The beneficial effects of massage not only come from the mechanical expression of thickened or purulent secretion, and the softening of adhesions, but from the stimulation and improved circulation which follows, with absorption of inflammatory infiltrations. Inasmuch as the prostatic urethra shows varying degrees of inflammation in most cases, massage is often followed by the instillation of a mild antiseptic into the posterior urethra. The urologist frequently fills the bladder with an antiseptic solution before massage is done. Certain other urological procedures may be necessary such as dilatation, the relief of stricture, or direct application of medicaments to the urethra. Of late years physiotherapy in its various forms has received recognition in the treatment of this condition. Vignal[11] has employed the high frequency current, diathermy, and Roentgen-ray therapy. He quotes Wetherer who gives statistics covering

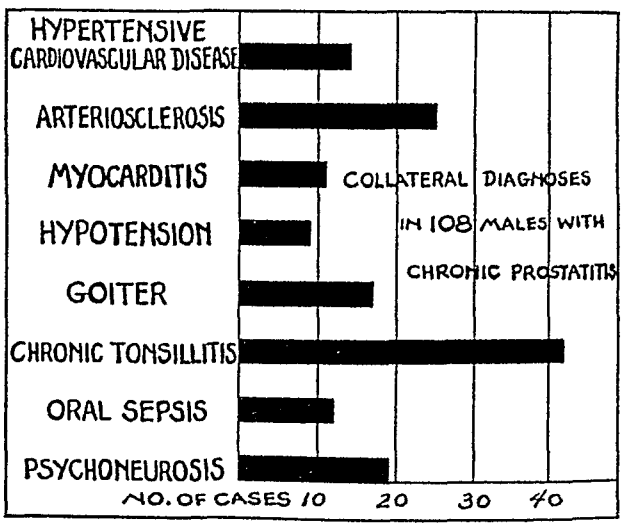

Chart No. 3

the treatment of 956 patients by means of the Roentgen-ray. Finally, a search should be made for other foci of infection which may be keeping the prostatic disease active, in order that these foci may be eradicated wherever it appears reasonable to do so.

Conclusions:

1. The routine examination of a male is incomplete unless it includes an investigation of the prostate gland by finger and microscope.
2. Chronic prostatitis is one of the commonest conditions present in adult males.

THE RECOGNITION OF THE MORE COMMON NERVOUS AND MENTAL DISORDERS*

By CHARLES ROSENHECK, M.D., NEW YORK, N. Y.

THE vulnerability of the central nervous system to noxious influences expresses itself, figuratively speaking, from the cradle to the grave. The pediatrician in particular always works in a fertile field of rigid necks, palsies and squints, Brudzinski and Babinski phenomena, Kernig's sign, convulsive reactions and stupors, so that a discussion of nervous disorders in infancy and childhood may, I hope, serve as an introduction to the subject. It is my purpose in this manner to include the major specialties, to address each specialist in turn, and to help him interpret the language of the central nervous system.

Due to the incomplete development of the architecture of the brain in childhood, and the resultant loss of inhibition, a release phenomenon which expresses itself in convulsive movements is very common in childhood. This may be purely reflex from distant points of irritation which is not under consideration at present, or what is most likely, it may usher in an acute infectious disease of the central nervous system. I am also omitting from consideration extra-neural processes which are ushered in by convulsive manifestations. A good differential point whether the convulsion is of a benign type or is the forerunner of an inflammatory disease of the cerebrospinal axis, is the state of consciousness. If this is lost, and the loss is continuous, it speaks for inflammation. Obviouly the presence of signs such as rigid neck, Kernig's phenomena and reflex changes readily corroborate the diagnosis. The type of infection can only be determined by appropriate studies of the cerebrospinal fluid. It might be well at this point to stress the fact that lumbar puncture and the examination of the fluid contained in the subarachnoid spaces of the cord is a "veritable biopsy of the central nervous system" and should be resorted to as routinely as one makes blood counts or urine examinations. Not all of the infections of the central nervous system give clear cut clinical evidence of their presence. A lumbar puncture quite often helps in obscure or ill-defined cases which for some reason or other fail to yield neurologic signs indicative of involvement of the neural axis.

The most common infections are cerebrospinal meningitis, tuberculous meningitis, anterior poliomyelitis, and the various encephaliditis. The secondary types due to otitic disease or sinus involvement are not under consideration. These express themselves dramatically enough and are readily recognized.

Text-books are wont to stress the fact that cerebrospinal meningitis and poliomyelitis are apt to come on acutely and that tuberculous meningitis is essentially insidious in its development. Although this is true for most cases, the reverse is true in many instances. A striking instance of this was the case of a child who had an undetermined knee joint swelling, which was manipulated for some unexplained reason. Within twenty-four hours signs of an acute meningitis developed, with death in one week. The postmortem revealed a frank tuberculous meningitis.

A difficult situation arises when poliomyelitis presents itself in endemic form. It may simulate influenza, gastroenteric disease or some undetermined febrile disturbance. It is only when paralysis develops that the true nature of the disease is recognized. To recognize the malady in the preparalytic stage is at times difficult but always possible if one notes carefully the presence of root pains, meningeal phenomena and reflex abnormalities. The spinal fluid examination helps tremendously.

The various encephaliditis—epidemic and toxic—are quite common in childhood and tax the diagnostic acumen of both neurologist and pediatrician. The absence of meningeal phenomena in both is worthy of note. The cellular reaction in the spinal fluid is very often within normal limits or slightly increased. The epidemic type limits itself as a rule to midbrain, basal ganglia and brain stem. Somnolence or insomnia may be present but rarely stupor or loss of consciousness. The outlook for recovery in epidemic encephalitis is good, but conduct disorders, personality changes, or the Parkinsonian syndrome, are the inevitable sequelae. Toxic encephalitis affects the cortical elements, producing stupor, loss of consciousness and a high mortality.

A distinct type of encephalitis—the socalled infantile cerebral palsy of childhood—deserves special mention. This may be primary of obscure etiology or, as has been considered by competent authorities, a variant of poliomyelitis. Many cases however, are secondary to the acute infectious diseases of childhood. Paralysis of one-half of the body gives these cases their distinctive stamp. This remains as a residual for the rest of the patient's life, unless the attack is mild. In view of the fact that the encephalon is struck down in the developmental period of life, before the period of psychic evolution, arrest of mental development in various forms invariably occurs.

Syphilis of the central nervous system while not very common in childhood occurs often enough, and in much the same way as in the acquired forms of later life. I have seen menin-

*Read before the Clinical Society of the Jewish Memorial Hospital on March 3, 1931.

geal, vascular and myelitic forms or combinations of these. I have observed and reported cases of juvenile tabes and juvenile paresis. With certain exceptions they do not differ from cases seen in adult life in their behavior and the objective neurologic signs. The serology of the blood and spinal fluid in all forms of neurosyphilis of childhood shows a higher degree of positive reactions than in the adult types.

The diagnosis of amaurotic family idiocy, should be suspected when an infant previously in good health and mentally alert, becomes listless and apathetic, shows gradual widespread motor weakness of the extremities, is apparently insensitive to visual stimuli, and shows the characteristic cherry-red spot in the macula. The deep reflexes gradually diminish, and when the disease is fully developed, they disappear entirely. I have been impressed by the fact, that this affection is not as common as it was in years gone by.

Neoplasms of the brain are common enough in childhood and should be suspected, in the presence of unexplained continued headache, persistent vomiting without cause, motor disability and difficulty in the maintenance of posture or balance, convulsions, conduct changes, stuporous attacks, or mental deterioration. Choked discs may occur very early or very late, depending on the location of the growth and its interference with the normal flow of the fluid in the ventricular system. In contradistinction to the common event of tumors of the brain in childhood, their rarity in the cord, has been the experience of most neurologists. The only case I have ever seen (a girl of 12) is at present under my care. The pensori-motor paralysis developed within two months after the onset of insignificant pain of a root character in the upper chest. A laminectomy revealed an epidural growth which proved to be a hemangioma.

The surgeon unless he bear in mind the possibility that diseases of the brain or cord in their initial symptomatology may produce purely pseudo-visceral disturbances, will often operate in the belief that certain intra-abdominal organs are the seat of pathological changes. As illustrative examples, I may cite a case of persistent vomiting upon which a gastroenterostomy was performed, in spite of the insistence of an internist that the cause of the vomiting was not due to intra-abdominal disease. Subsequent events proved the internist's contention. A brain tumor which for the time being had failed to give cerebral signs, explained the distressing and continuous vomiting. Another recent case concerned the performance of an operation by an experienced surgeon for a supposed hernia, which was undertaken to relieve persistent pain. The continuation of the symptoms led to a more careful examination which revealed the source of the disturbance, in the spinal roots. A meningo-radicular lues revealed the etiology. The unequal patellar reflexes and the pupillary anomalies, were just as accessible to the surgeon as to the neurologist.

The tabetic and the patient with spinal cord tumor are very often subjected to useless surgery, before the true nature of the disease is recognized. The tabetic less so than the patient with tumor of the cord. It is relatively easy to recognize a tabetic. Absent patellar and achilles reflexes plus Argyle-Robertson pupillary phenomena can mean nothing else. The cord tumor case is not as easily recognized. This of course applies to the early stages when irritative phenomena limited to one or more roots are the only symptoms. It is on this stage that most operative procedures have been undertaken in the mistaken belief that a diseased gall bladder, appendix or other abdominal viscus was responsible for the painful symptoms. Obviously when cord compression has occurred and paralytic and sensory phenomena are present no such error is likely to occur. It is in the pre-paralytic stage that the surgeon should bear in mind the possibility of cord neoplasm. I know of no easy way to impart such information to the surgeon. The persistence of pain limited to the distribution of one or more root segments, with sensory disturbances either in the root area involved, or more distally if the long fibre tracts of the cord are compressed, plus reflex anomalies either deep or superficial should arouse the suspicion of cord neoplasm.

The various visceral crises that occur in tabes should always be borne in mind by the surgeon. They may antedate the development of the tabetic signs by years although this is most unusual. I have the record of a case of persistent abdominal pain and vomiting, which was attributed to a diseased abdominal viscus. It was my privilege to examine this case neurologically and found nothing indicative of central nervous system involvement. Within a few years a picture of dementia paralytica unfolded itself. In retrospect the nature of the pain and vomiting were readily explained as crisis of central origin. A very common source of root pain which mimics intra-abdominal disease so faithfully that the surgeon is often tempted to operate, is the radicular syndrome secondary to spondylitis of the vertebral bodies. The radiating character of the pain which one would expect in root irritation is not always present. The pain may be sharply localized over an abdominal viscus and tenderness may also be present upon deep pressure thus deluding even the most experienced surgeon. I have had the privilege to see several cases that had been operated upon, with negative findings. A more careful checkup after the operation revealed the true source of the disturbance. *X*-ray of the spine is as a rule negative in the early stages of spondy-

litis. A diagnostic point in obscure cases of abdominal pain is spinal muscular rigidity and limitation of spinal movements.

The internist confronted with similar material as the surgeon, is apt to make similar deductions unless he bear in mind the possibility of neural pathology. In view of his natural conservatism in the treatment of visceral disease, and his wider knowledge of neurologic signs and symptoms, he is not apt to err on the side of radical measures.

The recognition of organic nervous disorders by the internist is obviously important. The busy internist is asked to see a variety of medical conditions, embracing almost all branches of medicine. In this way, considerable neurological material comes under his observation. This ranges from a simple neurosis to an obscure disease of the brain or cord. Let him bear in mind that disturbed neural function of an organic nature always manifests itself as alterations in pupillary outline inequality and sluggishness to light stimuli, decrease or increase of deep reflexes, Babinski phenomenon or its modifications, sensory alterations, palsies, atrophies, involuntary movements of abnormal types, embracing all varieties of chorea, athetosis spasms and tremors. The development of disturbance in gait, either spastic, ataxic or combinations of both, difficulty in executing movements that are usually smoothly and coordinately performed, are signatures of organic disease of the central nervous system. The diagnosis as I have elsewhere indicated is unimportant for the time being. The significance of such signs is to be borne in mind.

On account of the frequency of brain complications in ear, nose and throat conditions, specialists in this field have widened their knowledge of neurologic conditions to an amazing degree. Meningitis either circumscribed or generalized and suppurative encephalitis are seen by the otologist and readily recognized. The association of neurologist and otologist has, I am sure, been mutually beneficial in the evaluation of disturbances in their respective fields.

The neurologist is often asked by the otologist to examine cases postoperatively in which convalescence is delayed or the development of neurologic symptoms manifest themselves concomitant with sinus or ear pathology. A careful interpretation of all factors is obviously essential particularly where a decision has to be made for or against operative intervention. The desperate and very often fatal nature of brain complications makes it imperative that a radical attitude be adopted toward most cases that present neurologic signs either of a focal or generalized nature. Thus a ptosis, ocular palsy, facial pain, neck rigidity, Kernig phenomenon, confusion, clouding of consciousness or reflex alterations are significant and must be interpreted in relation to the clinical background of the original infection.

In these situations examination of the spinal fluid is of great value when the subarachnoid spaces have been invaded by bacteria, nothing is to be expected in most instances from operative interference. When the fluid remains sterile and simply shows cellular increase, the outlook in these cases after operative interference is much brighter.

To the ophthalmologist, the presence of pupillary inactivity, oculo-motor dysfunction and, above all, swelling of the nerve head should indicate to him the neurologic background of the disturbances. This may range from a simple inflammatory condition, such as encephalitis, degenerative diseases like tabes or multiple sclerosis to neoplastic or destructive processes involving the brain parenchyma.

In a general way, the specialties which have been omitted in this discussion except in certain specific instances, are not beset by any particular neurologic difficulties. The same principles of observation and interpretation, heretofore discussed, obviously apply to those engaged in those respective fields of specialization.

Due to the complexity of modern life with its many distractions, mental disorders are on the increase. The recognition of such conditions particularly before the development of frank psychotic symptoms is of great importance. It is the pre-psychotic state that we must all strive to recognize, for at this time a good deal may be done to ward off the final psychic disorganization. Even the recognition of such pre-psychotic trends and the institution of early treatment obviously do not always prevent the development of the full psychosis but may do so in many instances.

Psychosis may be roughly divided into 2 great groups—the emotional and organic. As you have already surmised, the former are primary and purely a disturbance of the affect or emotions, and the latter are secondary to organic disease of the brain. A third group are the so-called toxic-exhaustion forms which I mention independently in view of their occurrence secondary to toxic or constitutional disease. A careful analysis of all the factors involved in a given psychosis is of importance, in determining the background of such psychotic manifestations. One may see a præcox, manic-depressive, paranoidal, or confusional reaction in frank organic brain disease, when as a rule one associates such mental alterations with the purely emotional insanities. As an illustration, I may cite, a fact familiar to all neuro-psychiatrists, i.e., the admission of cases to institutions and classified under the emotional insanities, which on postmortem reveal brain neoplasms, as the cause of the psychosis. Quite recently I was asked to see a case that seemed to me one of simple depression. This was confirmed by the Bellevue psychiatric staff, and an increasing number of neurologists who were consulted. After a few weeks the patient suddenly

became stuporous, developed choked discs, and died. No postmortem was obtained but the inference that a neoplasm was at the bottom of the so-called depression is quite plain. I cite these facts to prove that similar psychotic disturbances may be caused by such diverse situations, as an emotional upset or a more grave organic brain disease.

Here again I want to stress the fact as I did in the early part of my discussion on nervous disorders that the recognition of psychogenic symptoms is of more importance for the time being than the diagnosis.

Personality changes, delusional trends, mood swings, bizarre behavior unmotivated, emotional reactions, pre-occupation with bodily functions, morbid ideas of a subjective character or directed toward members of the immediate family, illogical reasoning, defective insight, etc., all indicate disintegration of normal psychic processes. Bleuler has aptly said that insanity is simply an exaggeration of normal human reactions. If you are able to detect that "exaggeration" and evaluate it in relation to the make-up of the individual and his previous course of conduct, you will readily recognize psychotic behavior.

The time limit imposed upon me prevents a discussion of the psycho-neurosis, the mechanisms of which have been more clearly understood since the epoch-making contributions of Freud and his followers. The English have aply called these the minor psychoses. Due to inherent defects in the make-up of the individual, mainly of a biologic nature, he is unable to adjust himself to the demands that bodily functions make upon his psyche, or to his environment. In contrast to the psychotic who is constantly at war with the world about him, and blames these forces for his failures the psycho-neurotic is in constant conflict with himself, and invariably holds himself responsible for his failures of adaptation. His sense of realization is never disturbed, although he harbors endless fears, obsessions, and compulsions. His actions are colored by an atavistic infantile behavior common in primitive man and uncivilized races. In spite of what has been said the borderline between a psycho-neurosis and a pure psychosis cannot be too sharply drawn, as one occasionally merges into the other.

That numerous psycho-neuroses are the result of somatic disease, infections, endocrine disorders, constitutional disorders, etc., should always be borne in mind and a search for such factors is always to be advised. By the same token the danger of perpetuating a psycho-neurosis should also always be borne in mind if the physician in a mistaken zeal treats pseudo-physical complaints and disregards the psychogenic origin of such disorders.

The difficulties are many in the recognition and treatment of the psycho-neurosis and the final word on the subject will not be said for a long time.

In conclusion I trust that I have imparted to you some of my experiences in the detection of nervous and mental disorders, and help you recognize such signs and symptoms whenever confronted by them.

A TYPHOID INVESTIGATION

By FRANK W. LAIDLAW, M.D., MIDDLETOWN, N. Y.

A circular letter to health officers from the office of the District State Health Officer.

IN our time we have made somewhat strenuous efforts to impart to health officers and public health nurses the fundamental principles of this subject. Our efforts have not always been "crowned with success."

It is, however, refreshing to receive occasionally a report in which the conclusion is based wholly upon assumption.

Recently we asked a nurse to investigate and report on a *single case* (always more difficult than a group.)

The data secured showed that the case had, within the period of incubation, *attended the funeral of a victim of typhoid.*

It would be interesting to know how many investigators would have *stopped at that* and considered the investigation completed and the source *satisfactorily established.*

But this nurse didn't stop there. She continued the inquiry to the point of ascertaining that the new case had partaken of a lunch served at the house of the deceased before or after the funeral.

Here was another very enticing *stopping point* and one which would have appealed with irresistible force to something like ninety-nine per cent of investigators.

In this instance, the inquiry was continued to ascertain *who had prepared that lunch, GETTING BACK TO PERSONS.* It was found that the lunch had been prepared by a person from whom a positive specimen had been obtained in a previous investigation, in which this nurse had not participated.

It's an open book when you have the facts, but you don't get the facts without going after 'em.

RESULTS OF TREATMENT OF TOXIC GOITER FROM STANDPOINT OF BASAL METABOLIC RATE

By GEORGE M. GOODWIN, M.D., and MORRIS K. SMITH, M.D., NEW YORK, N. Y.

WE purpose in this paper to review the experiences of the Thyroid Clinic at St Luke's Hospital in the treatment of toxic goiter for the three years since October 1, 1927 This period is chosen because it coincides with the organization of the clinic in its present form with membership from both the medical and surgical services.

In recent years a great improvement has occurred in the diagnosis and treatment of thyroid toxaemia brought about by the application of methods of testing the basal metabolic rate and by the administration of iodine in the form of Lugol's solution.

The determination of the basal metabolic rate has been particularly useful in separating the cases of pure nervous instability from the true case of hyperthyroidism. It is recognized that two elements compose the syndrome of exophthalmic goiter. One of these results from disturbance of the nervous system the other from disturbance of the body metabolism. These patients present the problem of differentiating between a purely functional nervous disorder and hyperthyroidism. The estimation of the basal metabolic rate has made it possible to classify these cases with a confidence previously not possible. There is of course, a question as to whether a diagnosis of hyperthyroidism is possible in the absence of definite increase in the basal metabolic rate. We cannot go into the question of whether these patients with nervous instability who resemble the true toxic thyroid patient suffer from disturbance of the thyroid of different variety from the type manifesting both nervous and metabolic disturbance. From the standpoint of diagnostic accuracy and for practical purposes of treatment the diagnosis of hyperthyroidism should not be made in the absence of increased metabolic rate. In accepting this diagnostic criterion, however, one must remember that the nervously unstable individual is the type prone to develop hyperthyroidism and that the metabolic disturbance may become engrafted later upon the nervous disorder during continued observation. It is our own feeling that a diagnosis of hyperthyroidism is not proven unless both elements are present. It has been our own experience also in cases in which we have had the opportunity to see the disease develop that in the incipient case of hyperthyroidism, even in the individual previously of stable nervous type, the nervous disorder antedates the metabolic disturbance.

The upper limit of normal for the basal metabolic rate as usually given is +10 per cent. In our experience +20 per cent is a more accurate upper level of normal and in cases with metabolic rates between +10 per cent and +20 per cent we are never sufficiently convinced of the presence of metabolic disturbance to make the diagnosis of true hyperthyroidism. In fact we feel that readings between +20 per cent and +25 per cent should be repeated once or twice since the nervous patient will often give a reading of this kind on the first test and a normal rate on repetition of the test.

The metabolic rate seems to us to form the most reliable criterion upon which to judge the progress and the efficacy of therapy in a given case. The pulse taken under the same conditions as those under which the metabolic rate is tested is a valuable index but more susceptible to fluctuations than the basal metabolic rate and quite unreliable when taken under clinic routine. The introduction of an index such as the metabolic rate by which to judge a patient's course has supplied a definite criterion for the comparison of operative and non-operative types of therapy. Part of the difference of opinion as to the relative merits of different types of therapy has arisen from the variation in severity of the toxaemia. It is futile to compare the course of a case with a metabolic rate of +25 per cent with one whose rate is as high as +50 per cent. It has been well demonstrated that mild cases often run a self-limited course with spontaneous cure. The basal metabolic rate supplies a standard by which cases may be grouped for purposes of comparison and by which therapeutic methods may be judged. The basal metabolic rate while it has established a strict requirement of surgery—prompt and permanent reduction of the rate to normal—has also provided an opportunity to convince its opponents of the efficacy of operative therapy.

Many patients a year or more after the first observation may show great improvement or restitution of health regardless of the type of therapy. There is a difference as to the efficacy of a therapy as to whether the improvement has been gradual as indicated by a gradual fall of the basal metabolic rate over a period of months or whether the therapy has resulted in an abrupt and continued reduction in rate from the institution of the therapeutic method.

A factor which has had great influence in increasing the popularity of surgical therapy has been the introduction, by Plummer, of the administration of iodine in preparation of cases for operation. He chose Lugol's solution as the vehicle for iodine administration, although this particular preparation probably has no advantage over other vehicles containing the same iodine dosage. At the Mayo Clinic the use of Lugol's solution resulted in striking reduction in opera-

tive mortality. Naturally there has been a tendency to adopt iodine as an agent for the cure of hyperthyroidism, but most authorities agree that in severe and moderately severe cases it produces a temporary not a permanent remission of symptoms and that often such a remission cannot be obtained in an individual case more than once. It is doubtful whether its administration in mild cases alters very much the spontaneous course. It is difficult to understand why an agent which has such a striking effect temporarily does not establish permanent control over the disease, but it is evident that its usefulness is in the production of a remission of symptoms during which the safety of operative procedure is considerably increased.

For a long time the fear of post-operative myxedema forced upon the surgeon a conservatism in the reduction of thyroid tissue which not infrequently defeated his purpose as regards the prompt and permanent relief of symptoms. It was recognized later that except in total ablation of the gland the thyroid has a strong inherent tendency to regenerate. The history of surgery shows in general a progression in the amount of thyroid tissue removed up to the present subtotal resection. At first the surgical procedure consisted of a lobectomy and then later sub-total thyroidectomy. The term sub-total thyroidectomy may or did have a very elastic interpretation and there is no doubt that in many so-called sub-total resections considerable amounts of thyroid tissue were left. The operation as standardized at the Mayo Clinic according to Pemberton[1] consists in leaving thyroid tissue equal in amount to 1/6 to ⅔ of a normal gland. A normal gland averages about 25 gm. in weight and leaving ⅔ of a normal gland is very different from leaving ⅔ of goiterous gland weighing 200 gm. or more. Our own experience has led us to increasing thoroughness in thyroid resections up to the conception of a sub-total as expressed above.

The patients upon whom the conservative thyroidectomies were done usually showed definite symptomatic improvement and in six months or a year often had acquired good restitution of health. But their metabolic curves during this 6-12 month interval often showed a gradual descent to the normal level indicating a gradual recession rather than abrupt termination of the toxaemia. This type of response to surgery, with its attendant risk, was not impressive when compared with the course of cases treated with *x*-ray or cases which ran a course to a spontaneous cure.

At this time, which was before the use of Lugol's solution had reduced the operative mortality so remarkably, many of our patients were offered *x*-ray therapy. We have in our own records carefully followed histories of 16 cases (Chart I, B) in which the eventual restitution of health has been equally as good as our surgically treated cases and among these cases are some who have been referred to the Radio-therapeutic Department because of a continuation of symptoms after conservative thyroidectomy. These cases with continuation of symptoms after thyroidectomy seem to respond especially well to *x*-ray therapy.

Our objection to *x*-ray, like that of others, has not been that eventual restitution of health did not occur but that too much time is consumed in obtaining the result. Indeed since it has been demonstrated that a certain number of cases of hyperthyroidism run a self-limited course to a restitution of health it is difficult, in the individual case, to prove the influence of an agent which takes as long as radio-therapy in bringing about the termination of the toxaemia. Cases of our own in which we have seen a toxaemia drag on for over two years in one instance and for 18 months in another and show marked improvement after three months of radio-therapy convince us of the efficacy of this treatment though we cannot supply statistical proof.

We believe that *x*-ray therapy has a definite place in the treatment of thyroid toxaemia parpicularly in the cases of mild type provided they show a tendency to improve under careful observation. It is difficult to set an arbitrary standard by which to classify the mild cases although we feel that cases of exophthalmic type presenting a metabolic rate below 40 may be so classified. The objections to this conservative treatment of mild cases are the loss of time if treatment is unsuccessful, the danger of precipitation of fatal thyrotoxic crises by intercurrent infection or mental shock, and of the development of permanent cardiac irregularities.

We have already mentioned the two factors which in recent years have acted to increase the popularity of surgery over other types of therapy in the treatment of toxic goiter. In the first place preoperative care and the administration of iodine have greatly reduced the special hazards of thyroid surgery. In the second place the observation of the course of the toxaemia with the metabolic rate as an index has supplied a standard for judgment of therapy. The effect of successful surgery on the metabolic course has shown advantage over the more conservative methods.

There are of course to be considered in the evaluation of surgical therapy certain disagreeable sequelae. Among these is the development of a permanent hypothyroid state. This to be sure, may be controlled by the oral administration of thyroid preparations, but the artificial supply of the thyroid secretion falls short in the maintenance of normal health as compared with the adequate supply of natural secretion. In the main the other complications of surgery are injury to the recurrent laryngeal nerves and to the parathyroid bodies. These are complications which occasionally happen in the hands of the

Chart III.

most skillful but are rare when the surgeon is constantly on guard against them.

There continues to be a good deal of difference in opinion as to the respective merits of the operative and non-operative treatment of exophthalmic goiter. There are some who hold that thyroidectomy is to be avoided under any circumstances, others who aim to avoid thyroidectomy if possible and to resort to it only in the presence of long continued symptoms and lastly those who recommend thyroidectomy for every case showing a definite thyrotoxic syndrome. Recently the latter method has become increasingly popular because of the impressive statistical experience of many surgical clinics, although in going over such statistics one would like to find a more detailed and continuous follow-up study than is often presented.

It has been our policy since October 1, 1927 to advise surgery in almost every case presenting a definite thyrotoxic syndrome. On October 1, 1930 we undertook to review the results of this therapeutic policy in order to determine with what success we had approached the expectation of a low operative mortality, prompt and continued reduction of the metabolic rate within normal limits, relief of nervous symptoms and the avoidance of disagreeable post-operative sequelae.

Judgment of the efficacy of a therapeutic method depends in a large part on the follow-up of cases. Complete success would consist in following every case for a period of years. Such success is difficult to even approach. After their discharge from the hospital control of the patients becomes difficult for many reasons. If dissatisfied with the result of their treatment they may go elsewhere although in our experience the cases in which poor results are obtained are more apt to continue under observation than those who are well and see no reason from their own viewpoint to return. Many patients return to their occupations and have not the time to appear at the clinic.

We shall consider the cases of exophthalmic goiter and those of adenomatous goiter with hyperthyroidism separately for whether or not the two types are pathological varieties of the same disorder we feel that in their symptomatology and response to treatment they present definite differences.

Seventy-eight cases of exophthalmic goiter have been operated upon. In five of the cases stage operations have been done. In one of these the first operation was a ligation, in the remaining four the first operation consisted in resection of one lobe with or without the isthmus. At the second operation the resection was completed. The judgment of the operator must be especially exercised in deciding whether to complete the operation at one time. It is wiser to defer the resection of the second lobe if the patient's condition is unsatisfactory. The improved condition of patients after preparation with iodine has undoubtedly led to over confidence as to what they can withstand. In the charts operations which have been done in stages have been counted as one operation. One case has had a second operation, a year and a half after the first, for continuation of symptoms (13a-b).

Mortality: In this series of 78 cases of exophthalmic goiter there have been two post-operative deaths giving an operative mortality of 2.6 per cent.

The first of these two was a woman of 36 with an admission basal metabolism rate of +42 per cent which came down to +25 per cent on iodine preparation. She was considered a moderately severe case. The operative time was one of the shortest in the series. During operation the pulse became irregular. She had a sharp but not alarming post-operative reaction. On the third day she developed embolism of the right femoral artery with subsequent gangrene and died on the fifth day.

The second fatality occurred in a woman of 59. Her history of thyroid symptoms extended back for five years. The highest basal metabolic rate while under observation was +24 per cent. There was some discussion as to whether she really had hyperthyroidism. As she had been under treatment in the hospital for some time for another condition and wished to avoid delay and as the toxicity seemed of such mild grade she was given iodine for two days only immediately preceding the operation. The resection was technically simple. The patient's pulse however became very rapid on the table. Post-operatively she developed high temperature, up to 106 F., pulse to 160 and a stuporous condition and died on the second day.

Restitution of Normal Basal Metabolic Rate:— The accompanying charts give in detail the basal metabolic records of the entire group. Chart I-C gives the number of patients, the average basal metabolism on admission and at such periods thereafter as the patients reported, the average weight gain, and the distribution of the individual rates which go to make the averages in brackets of ten. It will be seen that the average basal rate on admission was +49 per cent which after iodine preparation had fallen to +21 per cent. Almost all of the patients had post-operative tests before leaving the hospital usually between the 10th and the 14th day. The average residence in the medical wards prior to operation was two weeks so that the post-operative basal rate represents the metabolism on the average of four weeks after institution of treatment. The average of the post-operative basal rates is +4 per cent. This fulfills satisfactorily the requirement of prompt reduction of the basal metabolic rate to normal. It will be seen however that the average drop during the period of iodine prepara-

tion was 28 per cent while the drop occurring after operation amounted to 17 per cent although 42 per cent of the cases had rates above +20 before operation while only 8 per cent had a rate above +20 after operation. So far then as prompt reduction of basal metabolic rate is concerned this requirement was fulfilled in all but 8 per cent of 71 cases which had post-operative basals and this reduction occurred on the average of one month after starting treatment.

More important in judging the efficacy of operative therapy than the initial reduction of the basal rate is the permanency of this reduction. Unfortunately with the most conscientious effort at personal follow-up many cases are lost sight of and in a three year period of study a proportion of the cases are too recent to judge the permanency. In Chart II-B are listed all the cases which were found at some time subsequent to operation to have a metabolic rate above +20. Here it will be seen that 17 patients had basal rates above +20 per cent at some time subsequent to operation. This is a proportion of 23 per cent of the cases who have had post-operative basal metabolic tests. Their individual courses are given in this chart. This would indicate that in approximately one out of every four prompt and permanent restitution of normal basal metabolism was not secured. But if this standard is used as a criterion by which to judge operative and non-operative therapy it must be remembered that the restitution of normal rate in non-operative types of therapy is seldom abrupt and almost always improvement is a gradual process. This is illustrated by the slow downward metabolic course of the cases who received radiotherapy as depicted in Chart I-B. In this group of 17 cases with metabolic rates above +20 some showed normal rates on further observation while others had normal rates after operation and elevation in rate occurred later.

Grouping the cases which have been followed six months or less there are 37 of which 3 or 8 per cent have had a last basal over +20 per cent. For the period of seven months or more there are 37 cases of which 6 or 16 per cent have had a last basal over +20 per cent.

Relief of Nervous Symptoms: The relief of nervous symptoms, in which we include nervousness, emotional instability, lability of pulse, sweating and tremor, is naturally not susceptible of translation into figures as is the metabolic change. Individuals who have suffered from exophthalmic goiter are rarely free from some evidence of nervous instability. Indeed the nervous disturbance in exophthalmic goiter suggests that there may be a primary or independent pathological factor residing outside of the thyroid. In recording our results on the nervous factors we have from our knowledge of the patients estimated the grade on the basis of 1, 2, 3, 4. Individuals given grade 1 nervousness have the excitability and irritability associated with "high strung" persons and when tense may manifest instability of the vegetative nervous system in an increased pulse rate, sweating of the hands, flushing of the face or slight tremor. This degree of nervousness is not distressing, arouses no complaint, and does not interfere in the pursuit of the patient's occupation. Grade 4 indicates the degree of nervousness seen in cases which are severe but not in crisis. Between Grade 1 and 4 are the proportionate degrees of nervousness. In all the grades above Grade 1 the nervousness becomes a matter of complaint and of interference with the patient's occupation. It is exceptional for the intensity of the nervous symptoms not to vary directly in relation to increased or decreased metabolic rate.

Included in Chart III are the records of the grade of the nervous symptoms on admission and when last seen. Of the 74 cases of which we have post-operative records 17 have been graded as regards nervous instability as O. These patients have been free of the nervous symptoms enumerated. Forty-five, the great majority, have been graded as 1. These show some residual nervousness brought out by examination or inquiry but not sufficient to interfere with a sense of well-being or pursuit of occupation. Ten cases have Grade 2 nervousness, and two Grade 3 which have caused both economic incapacity and ill health. Of the twelve cases in which there has been failure to obtain relief of nervous symptoms six are recruited from the group of 17 in which the metabolic rate had not been reduced below +20. In six of them the metabolic rate was restored to normal. One of these developed a recurrence of a psychopathic state characterized by profound depression and melancholia, attacks of which she had suffered before operation. A second, four months after operation, developed a mental condition characterized by delusions and hallucinations in the presence of normal metabolic rate and a third showed marked lability of the pulse. Conversely six cases in which complete reduction of the metabolic rate was not accomplished showed a good result from the nervous standpoint.

Sequelae: Hypothyroidism—Chart II-A presents fifteen cases whose basal metabolic rate at some time has fallen below —10 per cent. Persisting hypothyroidism is a rare sequence considering the reduction of thyroid tissue in a subtotal thyroidectomy and indicates the inherent power of the thyroid to regenerate in response to the demand of the body. Many of our cases have passed through a phase of apparent hypothyroidism after thyroidectomy. Seen a month after operation they show marked weight increase and their faces are characterized by puffiness particularly of the eyelids. In the next month or two this picture disappears and their faces regain their normal appearance. In this period the hypo-

thyroidism is usually not severe enough in grade for them to have subjective complaints. Of the fifteen cases of this group with basal rate below —10 per cent there was only one to whom we found it necessary to administer thyroid and about whom we were fearful of permanent hypothyroidism. In this case (16) the rate fell to —25 per cent three months after operation. She was given thyroid medication with benefit but discontinued it of her own accord and her last basal after four months without medication was —8 per cent. This was a year and a half after operation.

Injury to laryngeal nerves: Two patients have had post-operative hoarseness beyond that due to tracheitis. Both showed cord paralysis on laryngeal examination which later cleared up. A third patient who was quite hoarse was not examined laryngoscopically but her voice also cleared.

We have had no cases of tetany.

Transient attacks of auricular filbrillation have been common after operation. Ten cases (nine in the exophthalmic group and one in the adenomatous group) with previously regular rhythm have had attacks of fibrillation lasting from a few hours to seven days. At one time these caused us some concern and we took the fibrillation as an indication for the energetic administration of digitalis. We no longer take this attitude and except in cases who have previously shown the irregularity with evidence of decompensation we find that this post-operative fibrillation terminates spontaneously in a few hours or a few days.

The group of cases of adenomatous goiter with hyperthyroidism is not large enough to deserve much discussion but our conclusions concerning them agree with reports of others dealing with larger numbers. Seventeen cases of this type have had thyroidectomy (Chart I-A). In toxic adenoma subtotal resection has been done as a rule. However in a number of our patients, who have had the disease on one side only while the other appeared normal, we have left the normal appearing lobe and have obtained satisfactory results. It will be noted from the chart that the average admission metabolism was lower in this group than in the exophthalmic group and that the average reduction in rate on iodine was only 15 per cent as compared with 28 per cent in the latter. There have been no post-operative deaths in this group but the series is too small to draw conclusions from this. One has the definite impression that these patients are more apt to be free of any nervous residua than the exophthalmic group. Only one of them is clinically unsatisfactory because of continued nervous instability and this was a patient with cerebrospinal lues.

The operative treatment of the toxic goiter case involves more than the administration of iodine and the performance of thyroidectomy. Our cases enter the medical wards on admission for observation and treatment. Here associated visceral lesions especially those of the heart are evaluated if present, and an effort is made to establish in the patients a spirit of confidence and to relieve them of the dread of the ordeal of an operation. After operation we insist on a convalescent care for them at the country branch for just as long as their circumstances permit. This amounts on the average to three weeks after discharge from the hospital. For two months after operation each patient is instructed to take ten drops of Lugol's solution a day.

Summary: In this series of 95 cases of toxic goiter treated by thyroidectomy there have been two deaths giving an operative mortality of 2.1 per cent. Both of these fatalities occurred in the exophthalmic group making its mortality 2.6 per cent.

Reduction of the metabolic rate below the level of +20 per cent has been accomplished in all but 17 cases of the exophthalmic group. The permanency of this reduction cannot be judged by a three year study. Of 37 cases followed for six months or less the last metabolic rate was found above +20 in 8 per cent and of 37 cases followed for seven months to three years it was found above +20 per cent in 16 per cent.

Of 72 cases of exophthalmic goiter of which we have a record of the nervous condition after operation 17 are free from nervous instability, 45 have residual mild nervous instability not sufficient in degree to interfere with a sense of well-being or pursuit of regular occupation and 10 have persistent nervous instability which results in ill health and economic incapacitation, of varying degree.

Fifteen cases of the exophthalmic group have shown metabolic rates below —10 subsequent to thyroidectomy but in only one of these was it necessary to administer thyroid for the relief of symptoms of hypothyroidism and in this case the rate returned within normal limits without continuance of the thyroid medication.

In the group of 17 patients with toxic adenoma the immediate reduction of metabolism has not been as striking as in the exophthalmic group but the late results have been very satisfactory. The gain in weight has been notably greater.

Conclusions: At present the basal metabolic rate furnishes the best criterion as to the progress of cases of thyroid toxaemia. An objective criterion of this kind forms a standard by which therapeutic methods can be judged and compared.

[1] Pemberton, J. deJ. Recurring Exophthalmic Goiter, *J.A.M.A.*, 94, 1483-9, May 10, 1930.

We wish to thank the members of the Surgical Staff of the Hospital whose cases we have included in this study and particularly Dr. Frank Mathews and Dr. John Douglas who have operated on many of the patients and have also contributed by encouragement and suggestion to the work of the Thyroid Clinic, and to Dr. W. B. Long, who has treated the cases with *x-ray*.

AN OVAL TROCAR AS AN AID IN CLOSED THORACOSTOMY FOR EMPYEMA

By JACOB SARNOFF, M.D., BROOKLYN, N. Y.

THE purpose of this brief article is to point out the great aid that may be derived by the use of the writer's new oval empyema trocar. (Fig. 1.)* The ordinary round trocar used in the closed method of empyema operations is at times too large to pass through a narrow intercostal space, especially in the very young. To obviate this difficulty, the writer has designed for that purpose an oval trocar and cannula which has the following advantages:

One can introduce an oval trocar having the same circumference as the round one in almost half the width of the intercostal space, thus enabling one to pass a No. 24 French catheter slightly flattened, through a space much smaller than required by a round trocar. Once this tube is passed, it will conform to the shape of the intercostal space irrespective of the shape of the trocar used. An oval catheter which may be procured** to fit the oval trocar is desirable however. By using an oval trocar, one is less apt to injure the intercostal vessels and nerves which lie in a groove on the inner aspect at the lower border

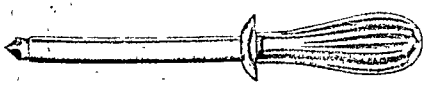

FIGURE 1
Author's oval empyema trocar.

of the rib, their relation being vein, artery and nerve, from above down. The writer has used this closed method with the improvements above mentioned with a much lower mortality and morbidity.

A few illustrations will enable one to visualize this simple technique of closed thoracostomy: The site selected is generally the seventh interspace in the posterior axillary line (Fig. 2). The empyema rubber shield is threaded over the trocar and cannula for a distance of an inch or two, depending upon the thickness of the chest wall. The trocar is then introduced into the chest cavity through a small skin incision about one-eighth of an inch in length, with its greater diameter in the direction parallel to the ribs. (Fig. 3.)

The trocar is then removed, leaving in the cannula. One should then get an escape of pus. A proper size catheter, preferably oval and bent at a right angle two inches from the tip, with a few perforations at its end, is introduced through the cannula into the chest cavity for a short distance. The cannula is then removed while the catheter

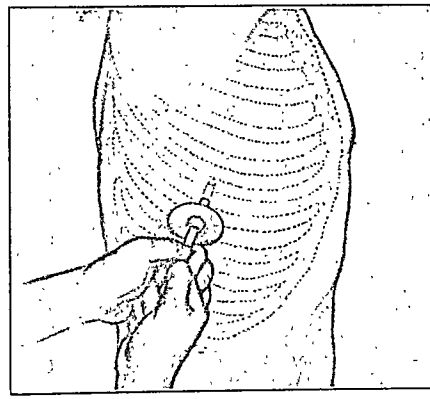

FIGURE 2
Trocar being introduced into chest cavity.

is being held in place. (Fig. 4.) The circular rubber shield is then sealed air tight to the skin with Johnson and Johnson rubber cement. One thus gets an air-tight fitting of the tube and a satisfactory drainage of the empyema through a good size opening.

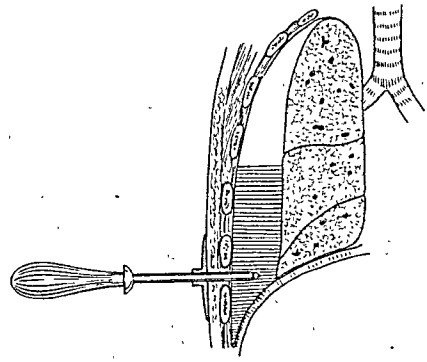

FIGURE 3
Trocar and cannula introduced into chest cavity. Rubber shield lies flat against chest wall. Trocar is above costophrenic sinus and below fluid level.

* Geo. Tiemann & Co., N. Y. C.
** C. R. Bard, Inc., N. Y. C.

The catheter is then connected to a longer tube which is placed in a bottle for drainage. This drainage may be in the form of negative pressure (Fig. 5) or subaqueous siphonage. The drainage is thus maintained for eight or ten days when leakage around the catheter generally occurs. At this time the suction or siphonage becomes ineffective and is no longer necessary. The

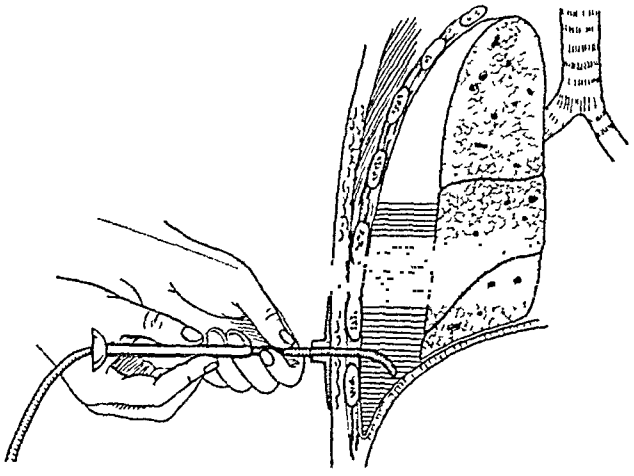

FIGURE 4

Catheter introduced into chest cavity and cannula being pulled out.

connecting tube may then be removed leaving in the catheter as a drain. During the course of about two weeks, the tube may be removed, depending upon the clinical course, X-Ray findings and the amount of discharge present.

The advantages of this closed method as compared to rib resection are:

1. It can be done in the most desperate cases and at an earlier stage with less shock.
2. It is a procedure requiring much less technical skill and less post operative dressings of the wound.
3. It is especially advantageous in double empyema where one may deal with both sides almost at the same time.
4. The oval trocar enables one to pass a good size catheter in all cases and thus obtain ample and satisfactory drainage.

Operation completed, drainage established, apparatus in situ.

THE PERIODIC HEALTH EXAMINATION—THE KEYSTONE OF PREVENTIVE MEDICINE*

By DONALD B. ARMSTRONG, M.D., ScD., NEW YORK, N. Y.
Fourth Vice President, Metropolitan Life Insurance Company

WHAT values does the periodic health examination hold for the individual lay citizen? That is the angle your chairman has asked this speaker to stress in this symposium. The health examination movement is not new. Increasing thousands are taking advantage of it and to a greater or lesser degree benefiting by it. Numerous arguments in its favor have been presented to professional and lay groups for many years. Of late, certain arguments in opposition to the health examination idea have appeared in the professional and lay press. In the opinion of the speaker the proponents of the idea still seem to hold the more attractive side of the discussion. Nevertheless, in a program where three speakers are to present the advantages of the periodic health examination, it is in itself a distinct advantage to come first. I am a little uncertain whether there are enough favorable arguments to go round, and consider it a fortunate privilege to have first choice, so to speak.

It would of course be more entertaining and exciting, if not informative, if this were a debate, covering the advantages as well as the alleged disadvantages of health examinations, but I fear that to stage such a debate under the auspices of a County Medical Society, committed to the promotion of the idea, would scarcely be seemly or appropriate! In any case the speaker is thoroughly convinced of the value of periodic health examinations. They are not of course, a panacea for all ills, nor will they detect or insure the prevention or cure of all ills. Yet the health examination is, potentially at least, the keystone of modern preventive medicine, and the nucleus around which the more important personal hygiene activities are likely to be developed.

I do not want to bore you with figures and statistics, yet there are a few statistical data that indicate in cold figures the value of periodic health examinations. I would like to refer first to the experience of the Metropolitan Life Insurance Company with the examinations offered to certain classes of policyholders. This medical service is, of course, purely diagnostic in character, the individuals being referred for further observation, diagnostic confirmation, and of course for advice and treatment, to their own private physicians. Such examinations have now been given to several hundred thousand policyholders, and it is significant to note that according to the reports of our actuaries, a specially studied group of those examined and presumably following their doctors' advice, has experienced a mortality which is 18 per cent better than the mortality among unexamined groups of legitimately comparable policyholders. For some age groups this mortality improvement is much greater than the average figure quoted, for the age group fifty to sixty years, for instance, the improvement being 53 per cent as compared with the general mass of comparable policyholders. Now, of course, the Company pays for these examinations and it is estimated that the return on the investment as measured in deferred death claims represents a saving of something like 200 per cent. This is a rather effective, though an impersonal, mass argument in favor of periodic health examinations.

Another experience of the Metropolitan Life Insurance Company may also be cited. Each year the Company requires all employees to have a thorough medical examination. Several years ago such a group of examinations was given to 7,530 employees, and the conditions found were carefully studied. In this group we discovered that 1,880 individuals had more or less serious defects or diseases. Each one was given what was considered to be the proper advice and urged to secure private medical treatment. A year later this same group was carefully reviewed and it was found that more than 50 per cent of the defects originally discovered had been corrected or overcome. The significance of this not only to the individuals concerned, but to industrial and commercial concerns who are desirous of conserving their human resources, must be evident.

One other statistical observation and then we will be through with figures. During the last twenty years or so there have been added about five years to the average expectancy of life at birth. This is largely the result of the control of certain of the major infectious causes of death, such as diarrhea and enteritis and other previously great factors in infant mortality; typhoid fever, tuberculosis, diphtheria, etc. Yet not only is it true that this improvement has been entirely confined to younger age groups, but it is even a fact that at the older ages the expectation of life has not only not increased, but during the last few years has actually decreased. For instance, at age thirty-seven, in 1921 the average individual in the United States might have expected to live 32.86 years. By 1927 his expectancy at that age had decreased to 31.47 years, or a decrease in six years of almost a year and a half! Various causes have been assigned to this phenomenon, but it seems to be a safe assumption that the experience is in large part

* Presented before a public meeting of the Philadelphia County Medical Society, March 25, 1931.

due to an increase in certain of the so-called degenerative diseases, such as heart disease, the kidney affections, cancer, diabetes, etc. It is true that the saving of life in the younger periods has pushed forward a larger fraction of the population into the older age groups, and of course we must eventually die of something. Nevertheless, there seems to be a real increase in certain degenerative diseases, and the significant thing is that most of these affections have small and apparently insignificant beginnings. In other words they have incipient symptoms that might in many instances be detected by a competent physician. Such early detection can in many cases lead to advice and treatment that may cure the condition, or may arrest its progress—thereby either saving and prolonging life, or deferring the date of demise. That this can be the case seems well supported by the previous health examination experience, largely among adults, cited from the records of the Metropolitan Life Insurance Company.

The health examination, in the opinion of its advocates, is applicable to all ages, and to all families. Its universal practice seems a preliminary requisite if we are ever to realize such desirable objectives as are embodied in the slogans "Every home a health center," and "Every doctor a health officer." Let us look for a minute at the composition and at the health and hygienic needs of the average family. In such a family there may be an infant of, let us say, three months of age. Even under the best of hygienic conditions, even when breast fed, such an infant may have beginning signs and symptoms of rickets, which the parents may not recognize. A visit to the doctor or the pediatrician at two or three months' intervals during the first year of life will serve to detect and check such symptoms and to insure the child's future freedom from the more serious symptoms or sequela of such a disease.

In such a home there may be a pre-school child, in whose case an examination at, let us say, intervals of six months, would detect enlarged and infected tonsils, the correction or removal of which might help to protect the child from future serious if not fatal attacks of acute rheumatic fever. The detection and correction of other physical defects should enhance the health and growth of the child and send him into the beginning years of his school life free to progress and to learn. In the same way an annual examination of the school child, either by the school physician or by the private family doctor, has many times indicated its worth. Let us not forget that here in Philadelphia and elsewhere the careful examination of groups of school children has disclosed not only a wide variety of serious physical defects, but a surprisingly high incidence of possibly latent but threatening signs of tuberculosis, thus bringing under clinical and hygienic supervision a group of children for whose future health and welfare such supervision is essential.

We have already said enough about the general advantages of the health examination to indicate what its importance may be for the adults in the family, both men and women. After all, a careful examination, followed by sane advice as to living habits, ought not only to prolong life—a thing in which most of us have only an abstract theoretical interest anyway, but should also materially enhance the joy of living, and should insure that our body mechanism would have a better chance to run smoothly and quietly for the remainder of our years.

Many analogies have been drawn indicating the significance of a physical examination in the light of other life experience. We are reminded that the average business man would not expect his business to operate indefinitely without an inventory or a stock taking. Presumably, it is legitimate to remind the business man that such an appraisal of his own body mechanism may be equally vital to its continued operation. We are reminded that no one would start on a long automobile trip without having the machine overhauled. Of course, we should not forget that each of us is always starting on what we hope to be a long journey and that it is precarious to start such a journey with the human steering gear out of order, or an improperly functioning carburetor, or unreliable brake bands. I might raise the question as to how many of us may have sand in our bearings or a knock in our engine, or possibly even a leaking radiator! Of course, the analogy of the human body to the machine is not a complete one, for in the case of the human body there are few if any spare parts. We cannot replace a permanently damaged heart. It is perhaps possible to buy "store teeth," but one could never purchase "store kidneys." We have to make the most of the equipment with which we are originally launched in life.

It becomes evident, therefore, that certain of the principal objects of the health examination might be itemized as follows:

1. The detection of defects such as those of the teeth, the nose, the throat, posture, etc.

2. The detection of incipient disease, such as cancer, and other diseases already mentioned. In the case of cancer let us not forget that at the start it is not a systemic disease. It is not, as claimed by the quacks, a "blood disease." Cancer always starts locally, and if that initial spot or initial growth can be detected before it metastasizes or spreads to other parts, its treatment or removal, with cure, is almost certain. Unfortunately beginning cancer rarely hurts and consequently the patient infrequently goes to the doctor early enough; but a regular checking over

by a physician will detect many cancerous conditions in time.

3. The establishment of health habits, as a result of the health educational opportunity which the periodic health examination offers the doctor He may find no defect and he may find no disease, but he may find undesirable habits of working, of exercise, of recreation, of eating, etc He may be able more advantageously to adjust the "fuel mixture" for the human carburetor, and he may aid in the establishment of good health habits that will not only prolong the life of the patient but increase his comfort and pleasure of living, even admitting that there is still much that we do not know about the physiological "rules of health."

4. The determination of our margins of safety is another vital consideration. May we remind you that the average normal infant starts life with a considerable excess of vital tissue He has, for instance, about seven-eights more kidney tissue than he really needs to perform the functions of the kidneys at that time. In the same way he has certain reserves of other vital organs Yet inevitably, these reserves are gradually cut into by various attacks and invasions, such as diphtheria, tuberculosis, or the stress and strain of ordinary living. Gradually, therefore, the individual uses up his margins of safety, and in one direction or another invades certain of his danger zones. Now, of course, what the health examination should do, is to point out these limitations. The role of the doctor is to be that of another Benjamin Franklin, who will seize this opportunity to teach Americans physiological thrift. He will point out to them their physiological limitations. To some he may say that the margin of safety in certain vital directions is still ample for full and reasonably unrestricted living. To others he may say that the limitations are narrow, that they must be recognized, and that we must step rather softly for the rest of our days.

5. And then finally, when the doctor finds no disease or defect, when his health advice is trivial, when the margins of safety are discovered to be great, and he is able to slap the patient on the back and tell him that he is "O. K." for another year, is there anything quite to equal the "grand and glorious feeling" which only this assurance from the physician can give!

On the other hand, as we said in the beginning, there are certain criticisms of the health examination movement, and certain criticisms of the way in which the medical profession is handling or mishandling this movement. One of these criticisms is that the health examination places too much emphasis upon physical welfare and physical symptoms; that it excites too much curiosity, fright, and introspection; that it results in worry, neurasthenia, and hysteria; that it is, in other words injuriously and often disastrously suggestive. It is no doubt true that most of us are open to influence by suggestion. Even doctors have imaginary diseases. I heard of one recently who was congratulating himself, saying that he did not know when he had felt so well, because he "had not had an attack of cancer for at least three months." You probably also have heard of the layman who had read all of the medical literature he could get hold of, and who admitted that he "had every disease in the list except house maid's knee."

It is true that we are all suggestible but the principal question seems to be: where shall we get our suggestions? Shall they come from a scientific source through the physician, on a basis of knowledge, and backed up by sound advice, or shall they come through quackery, through back fence gossip, through patent medicine advertisements, and through the ignorant imaginings of uninformed minds? It would seem that the former alternative were preferable. After all, we should not be afraid of facts. They should in fact relieve us from unfounded fears and afford us an opportunity to face real dangers intelligently. There is after all an application here of one of the world's greatest sayings: "Ye shall know the truth and the truth shall make you free."

The other principal point of criticism is aimed at the physicians who participate or should participate in health examination work, and in that connection I would like to conclude with a word or two addressed to the doctors who may be present. During the last few years I have seen a great deal of correspondence concerning health examinations, including masses of communications from laymen in which they are decidedly critical of the doctors to whom they have gone to have a periodic inspection. It appears to be true that the medical profession has not been overly alert in seizing this opportunity. It appears to be necessary not only to urge the public to go to the doctor for an examination, but it is also necessary to encourage the doctor to prepare himself to meet this public demand, to make a reasonably uniform and thorough health examination, to utilize the diagnostic services for the patient which his community affords, and to teach the patient such personal hygiene as the situation may indicate to be necessary. In other words the doctor must learn to practice preventive medicine.

There is, of course, another great medical need, that applies to medicine as an organization rather than to individual physicians, and that is the establishment of authoritatively controlled machinery for the direction of people into sound and reliable medical channels. Families move about a great deal these days. Fewer and fewer of them have long standing medical contacts. The family physician is relatively a rarity. Many of them want to know how to find a doctor, how to select a specialist, where to go for certain types of treatment, where to get a competent diagnosis,

where to secure a thorough health examination. Who is going to tell the layman who seeks this service where he can find it? This I believe is not the job of the private health organization, nor of the Health Department. It is to my mind a job of organized medicine, and particularly of the County Medical Society. Machinery should be set up to this end, and is now being experimented with in the Information Bureau and Medical Guidance Services of such county societies as those in New York, Brooklyn, and a few other places.

Let the doctor bear in mind that this field of preventive medicine is really enormous. It not only includes the health examination movement, but it covers the whole range of personal hygiene and pre-clinical medicine. It has to do with the physiological welfare of the patient, as well as his pathological manifestations. It may be concerned with occupational guidance. It must involve pre-natal advice, child hygiene, maternal hygiene, etc. It will even be concerned with mental health. It of course will cover the wide range of immunization activities, such as protection against diphtheria, typhoid fever and smallpox.

Previously and traditionally the doctor has been concerned with the layman only when he is sick. Increasingly in the future he will have to be concerned with him while he is well, and he will have to be interested in keeping him well. The kind of organization devices which we need at present are, first, those which will educate the public as to the value of the periodic health examination and will urge them to seek competent regular medical guidance; second, those which will advise the doctor as to the importance of this field, and point to the necessity for his preparation to meet the demands of the lay public for personal health inspection and instruction; and finally, those that will furnish for medicine in general the necessary organization for the fostering of the whole range of preventive medicine. There is not the slightest doubt but that the future is going to require of medicine a considerably higher and more complicated degree of organization, not only to meet the demands of preventive medicine, but to provide the needs of medical therapy. Medicine has social as well as individual obligations. To meet those obligations more organization of some kind is inevitable, and this organization will either gradually be developed by a socially conscious medical profession, alert enough to face the situation and to seize the initiative, or it may be carried out for the medical profession, perhaps beyond its control, by lay or state forces.

Medicine is criticized today because its services are costly, because they are unevenly provided, because no devices have as yet been worked out to insure the wide application of the instruments and methods of precision in diagnosis and treatment, and because its knowledge of prevention is ineffectively applied. The extension of the practice of health examination work by physicians, and their more generous participation in preventive work, will in part meet these criticisms. As a matter of fact if preventive work is sound it has a very direct bearing on the greatly agitated problem of the cost of medical care. After all it is cheaper to prevent than to cure, and the public is rapidly finding that this applies to medicine as to other things. On the other hand should the whole range of preventive medical activities be even partially developed, there would probably not be by any means enough medical men to meet the popular needs and demands. It seems very likely that the development of a reasonable amount of remunerative work in the preventive field would more than offset the inevitable financial loss to the medical profession that would follow an extensive application of preventive effort. A large part of the current criticism of medicine can be refuted if leadership can be found in the profession to open the doors into this great new field.

The periodic health examination is therefore not only the keystone of personal hygiene. It is also a vital anchorage for the current private practice of medicine. Finally, it is the entering wedge both for the doctor and the layman into the field of the private practice of preventive medicine, and organization for its adequate promotion might even point the way to at least a partial solution of certain of the very grave social and economic organization problems with which medicine is faced today.

ANNUAL MEETINGS

May is a month of annual meetings of State Medical Societies, those of eight States being listed in the Journal of the American Medical Association. The programs of these meetings as announced in the State Journals disclose a uniformity of plan and organization throughout the States. Physicians observe what their colleagues are doing in medical administration as well as private practice; and from among the varied experiments that are tried in the several States, they choose the best and make those procedures their standards of organization and action. A physician from California or Maine would feel entirely at home in the House of Delegates of the Medical Society of the State of New York.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 22

The Bassett Hospital Guild in Cooperstown, New York has aroused medical interest throughout the State, as well as the interest of the physicians and hospitals beyond the State. The outcome of the experiment is awaited to see what constructive information may be brought to the surface regarding the problem of the availability of modern medical care for those whose financial resources are not far enough above the necessities of life to pay for modern medical care and medical service themselves.

On Page 37 of the January 1, 1931, issue of the NEW YORK STATE JOURNAL OF MEDICINE there is a report of the proposed plan of the Basset Hospital Guild. On Page 96 of the January 15, 1931 issue of the Journal under "Presidential Comments on Current Events—No. 14," there is a discussion of the purpose of the Guild. Since the class of two hundred was only started on January 15, 1931, this comment, therefore, continues the discussion. (See page 653.)

Resolutions from the Otsego County Medical Society criticizing the Guild as unethical, as contract practice, and as unfair competition were considered by the Executive Committee of the State Society on December 11, 1930, and a resolution adopted that the Secretary of the State Society be authorized to write to the Secretary of the Otsego County Medical Society reaffirming the attitude of the State Society as opposed to contract practice and referring the rest of the communication to the Public Relations Committee for study and suggestions. During an informal discussion the counsel of the State Society stated that in his opinion nothing could be done in the matter by the State Society. A sub-committee was appointed by the Chairman of the Public Relations Committee to study the matter further.

On April 21 the committee attended a special meeting of the Otsego County Medical Society and heard a discussion of the Guild, taken part in by several members of the Society and one member of the staff of the Bassett Hospital. No important objection was expressed at this meeting. The Guild, as it has been conducted, has not interfered with the private practice of medicine. It was found that there were two physicians in the territory of this experiment. One lives in Cooperstown. He is said not to be unfriendly to the scheme. The other lives outside of Cooperstown and has two former patients in the Guild, but the matter was of little importance to him.

On April 22 the committee spent five hours at the Bassett Hospital in conference with the staff. The Guild has two hundred members. The hospital has agreed to give them medical care and medical service in the hospital or medical service in their homes, as the hospital decides, for twenty-five dollars for a year for individuals and one hundred dollars for a family, excluding chronic illness and obstetrics. The class was closed on January 15 so as to carry the study through one year with the same number.

While the Guild stated in its original circular that any individual under certain conditions might join the Guild, the membership is mainly made up of working men; and many of them, though they could pay a small fee to a private physician, would ordinarily go into the wards of a hospital. Some of them might pay the three or four dollars a day for ward service but could not without great hardship pay the usual charges for x-rays, surgical operations, laboratory examinations, electrocardiographs, etc. There are some people in the membership who would feel that they could not go into the ward and who would be financially embarrassed if they had to pay regular private patient rates. There are a few members of the Guild who could pay the regular rate for private patients. The group, as a whole, is not hemogeneous enough to make a general statement about their capacity to pay.

Approximately twenty-five per cent of the membership have been paid for in full or in part by well-to-do people taking out memberships for the very poor or by employers taking out memberships wholly or in part for employees.

It is not known what this experiment in social medical service will prove. The cost for the first two months of the period of observation has not exceeded the proportionate amount of the yearly fee. The period is, of course, too short for real information as to the cost of illness for a year.

The population of Cooperstown is three thousand and the area surrounding which might be considered as reasonably included is one thousand more, or four thousand in all. The Guild, with its membership of two hundred, represents five per cent of the population.

In organizing the group an effort was made to admit no one to the class able to meet without financial hardships the unknown hazards of illness. A few people financially able to pay for what medical service they get were so insistent that they were taken into the Guild with the understanding that if admitted to the hospital, they would pay the full private patient charges minus a daily deduction of the rate charged for ward service. Most of the Guild members were patients of the hospital previous to the organization of the Guild. It does not appear that the Guild, therefore, is in competition with the private practice of medicine. No one taken into the Guild admitted when questioned that he had been a regular patient of any other physician.

A contribution may be made to the cost of medical care for acute illness in a group of people who largely could not procure this for themselves except by an insurance method of distributing the cost of illness in the same way that the

cost of automobile or other commercial insurance is distributed.

This is the study of the sub-committee up to the present time. It was reported on April 23 to the Public Relations Committee who made the following suggestions.

Since the experiment points the way toward a method of making modern medical care available for those who might not otherwise have it, and at the same time provides for payment of the cost of technical instruments for diagnosis and treatment and the cost of medical service, it may be a contribution to the study of how these two things may be brought about.

It is desirable for the profession of medicine to know the results of this experiment. If it shows that the cost of acute illness can be distributed by a method that will provide modern diagnosis and treatment and compensation for professional work, it may be the beginning of a solution of one of the problems of medical service. It may have an influence in averting some other solution not as free from objection.

It is not probable that the class who are unable to pay for medical service will long be left to shift for themselves before some official agency undertakes to meet the problem.

The Public Relations Committee makes this interval report of its study and suggestions. At the end of the year's experiment it will report the results as they exist at that time.

The Public Relations Committee recommends that the profession await the results of this study to see if there is any light on the solution of one of the great problems of medicine.

WILLIAM H. ROSS.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Preventing Typhoid.—This Journal of May, 1906 contains the following editorial on the prevention of disease, especially typhoid fever:

"It is in the study of prevention of disease that medicine has no rivals and is the least apt to be misunderstood. This realm is not invaded by the charlatan or the pseudo-scientific sect. The "schools" of medicine have not to do with prophylaxis. They are not interested here. Intelligent and scientific effort in the prevention of disease is tangible and can be measured, and is free from confusion than is therapeusis.

"What has been done with cholera can be done with typhoid fever. The fifteen hundred persons who died of this latter disease in this State during the past year are a needless sacrifice, for medicine has developed the knowledge which, if applied, would make typhoid fever an obsolete disease. Politics alone stands in the way. If the medical profession were given *carte blanc* power to eliminate typhoid, it would be done. Medicine has perfected the knowledge of this disease and the means for its prevention, and the people want the disease stopped, but the legislative representatives of the people are busy with mergers and tariffs and appropriations and jobs while the pale faces of those fifteen hundred, dying of a preventable disease, are seen only by the profession of medicine. When some community is awakened by an awful epidemic, it arouses itself, and some petty local measures are applied, always successfully, to prevent the disease; but what is done for a country village should be done for the State, for the country and ultimately for the world—and the disease would end.

"This will be done—it should be done now, but it will not—and then typhoid will pass into history, a conquered disease. In the meantime, your son, on the threshold of life's work; and your daughter, with the roses of health in her cheeks; and your wife, the mother of the laughing babe; and you, to whom these observations are addressed, shall return in the autumn, and lie down on your bed and die, for the mergers must be put through, and the tariff must be tinkered, and the appropriations must be passed round."

MEDICAL PROGRESS

Treatment of Tetanus, Diphtheria, and Neurotropic Diseases by the Phylactic Method.—According to René Cruchet, if a guinea-pig is injected with a quantity of tetanus virus ordinarily fatal, this will produce no action provided that 12 to 15 minutes previously the animal has been under chloroform anesthesia for about 3 minutes. The chloroform impregnates the lipoids of the nervous system in such a manner that the toxins cannot become fixed in their turn. But if instead, the same injection is followed in 10 or 15 minutes by chloroform anesthesia, the guinea-pig dies more rapidly than after the injection alone, for the chloroform precipitates the toxicity of the serum. If, however, at the same time with or immediately after the injection of virus one of antitetanus serum is given (0.5 c.c. per 100 gm. body weight) the animal lives, since the injection renders the primary intoxication inoperative. Chloroform thus represents an agent of protection or phylaxis. This protective power does not exist to the same extent when the neurotropic toxins are already fixed in the nerve centers. Chloroform does, to be sure, take their place, but the organism, already considerably enfeebled, no longer has power, alone, to make the necessary antibodies for its defense. For clinical use, strong doses (50, 80, or 100 c.c.) of antidiphtheritic or antitetanus serum should be administered immediately before or during the chloroform anesthesia, using both subcutaneous and intraspinal injections, the former first. In the hypertoxic form of the disease one should not hesitate to give intramuscular and even intravenous injections, ending up with a subarachnoid injection of 10 to 30 c.c. It may be necessary to give the treatment twice in the first 24 hours, but generally once a day will suffice. The injections should be used as early as possible, before the nerve centers are too severely attacked, and while the organism can still fight. They may also be employed suit-
-ly in poliomyelitis and encephalomyelitis.
the latter, in the absence of serum, uro-
acts much the same as chloroform, but
are different, and might be fought
used through the organism by
if they remained fixed in the

de Médecine,

An Unusual Type of Diphtheria Carrier.—A. Victor Neale, writing in the *British Medical Journal,* February 28, 1931, i, 3660, makes the observation that by means of the Schick test it has been learned that the proportion of immunes among persons who have never had clinical diphtheria, living in different localities and belonging to different levels of society, has been determined. Broadly speaking, a much higher rate of immunity has been found among inhabitants of the poorer and more crowded districts. This may be attributed to greater exposure to subminimal infections with the disease virus through which immunity has been acquired. The possibility of such acquired immunity would be much less in people living in country districts where, although the incidence of the disease may be low, the chances of contact are much less. In support of this contention cases are cited which indicate incidentally that the immunization of persons living in country districts is as important as the immunization of town dwellers. In October, 1929, a boy aged 12 years had a mild conjunctivitis, with no general symptoms. During the period December 26, 1929, to January 26, 1930, one sister and four brothers developed very severe faucial and tonsillar diphtheria. The detection of a carrier in the household followed a casual remark concerning the previous eye condition in the boy with conjuctivitis. Careful examination of his left conjunctival sac showed a few fragments of membrano-purulent exudate, which on bacterial examination gave a pure growth of diphtheria bacilli. The child had never had any clinical diphtheria infection before. It would seem that he had obtained general immunity from the local conjunctival lesion, which had shown occasional recrudescences.

Treatment of Severe Acute Cholera Morbus in Adults.—Ludwig Veilchenblau states that in the course of his practice he has had six cases in which adults seemingly in good health were suddenly attacked with uncontrollable vomiting, abdominal pains and diarrhea, accompanied by weak, rapid pulse and threatened collapse, all supervening within a few minutes. He was able to recognize the alarming possibilities in these cases the more clearly through having chanced to attend a postmortem demonstration in just such a case. In these fulminant attacks there is no time for the customary opium drops or for the clearing out of the intestinal tract by calomel or castor

oil. In addition to cardiac weakness and gastroenteric symptoms, the loss of fluid leads rapidly to the familiar picture of cramps in the muscles of the calf. The physician is called upon for quick action to put a stop to the exudation in the stomach and intestinal tract. In his first case Veilchenblau apparently hit upon the right treatment when without loss of time he gave a morphine injection combined with digipurin, for the exudation stopped promptly and the vomiting and purging ceased. In another case where after brief relief the vomiting began again, he replaced the morphine with pantopon in the second injection, after which there was a cessation of all gastroenteric symptoms. In some patients there was a rise of temperature of 38°-39.4° C. In all there was extreme prostration and cardiac weakness, from which recovery was slow, requiring 8 to 14 days. These happy results are reported because in an unusual crisis of this kind, where prompt action is needed, the very simplicity of the remedy might cause it to be overlooked.—*Munchener medizinische Wochenschrift*, February 13, 1931

Minor Maladies.—Among minor maladies which are easily overlooked Charles Hunter mentions *hernia of the linea alba.* The possibility of this type of hernia should be kept in mind in all doubtful cases of epigastric pain of irregular character. The mere presence of such a tumor, however, does not mean that the symptoms are due to this. *Kinking of the splenic flexure,* being intermittent, frequently gives no hint of its presence. The diagnosis must be made from the history and the result of treatment. An ounce to an ounce and a half of castor oil is the best aperient. To prevent recurrence, flaxseed or psyllium seeds, two teaspoonfuls after meals, may be administered, with liquid paraffin at night. Worry, hurry, or indiscretion at meals, or insufficient sleep often precipitates an attack. *Cramping of the calf muscles,* which usually occurs in the morning when one is half awake and stretches himself, may be avoided by deliberately not stretching the foot on awaking—by avoiding the inclination to bring the toes down and the heel up. In obstinate cases a special shoe has been made for night wear to prevent dorsal extension of the ankle. Possibly the tight tucking in of the bed clothes may have something to do with this tendency. A little heeded, though not uncommon, ailment is *myalgia of the abdominal muscles* or fibrositis. Such cases are usually mistaken for chronic appendicitis, and operated upon, though a diagnosis of ovarian lesion, chronic gastric ulcer, or gall-bladder disease may be made. In these cases the pain usually centers in one small area. Aspirin and similar drugs are valuable in some cases. When the pain is severe, injection at the sensitive spot of a drachm to a half ounce of physiological saline solution, with 0.5 per cent novocaine added, gives satisfactory and permanent results. *Gluteal myalgia* may be treated in the same way when the tender areas are small and readily accessible, or massage may be employed. *Left inframammary pain* is a common condition, especially in women from 25 to 45 years of age. It is most important that the patient be reassured concerning her heart. In patients whose outstanding complaint is *chronic fatigue,* and in whom a searching physical examination reveals nothing to account for the condition, it is advisable to give a test breakfast to determine whether hydrochloric acid is absent. If so, 80 drops or more of dilute hydrochloric acid taken before meals may relieve the fatigue. The basal metabolism test may prove valuable in revealing an overlooked myxedema in which fatigue is the outstanding symptom. In these cases thyroid feeding is, of course, indicated.—*Canadian Medical Association Journal,* March, 1931, xxiv, 3.

The Relations of the Bile to the Total Metabolism.—R. Seyderhelm, writing in the *Deutsche medizinische Wochenschrift* of February 27, 1931, says that the bile is a peculiar mixture consisting on the one hand of metabolic refuse and on the other of building substances important for life. While the refuse leaves the body definitively, other ingredients are resorbed. By feeding the various ingredients separately to dogs that had been subjected to biliary fistula, Seyderhelm undertook to determine which of these substances would cure the consequent anemia. It was proved conclusively that it was not the bilirubin, the lecithin, or the cholesterin. The only active substances were found to be the bile-acids. The astonishing discovery was also made that the administration of light-activated ergosterin, *i.e.,* antirachitic vitamin D, in minute quantities cures not only the biliary fistula disease but also the osteoporosis and epithelial degeneration. The question arose whether ergosterin in light-activated form is also subject physiologically to a hepato-enteric circulation in the organism. Since the red corpuscles are known to contain ergosterin, it was conjectured that this ingredient, becoming free by autolysis, reaches the intestine with the bile, in association with the bilirubin and cholesterin of the red cells, undergoes resorption here, and then returns anew to the liver, together with the bile-acids, and into the general circulation. That this is actually the case was demonstrated when an alcoholic extract of oxgall failed to cure the fistula anemia, whereas an extract of bile that had been acti-

vated with ultraviolet rays succeeded in doing so. These results have been confirmed by Japanese workers. The hepato-enteric circulation of the bile-acids and ergosterin exerts a favorable influence both upon hematopoiesis and upon calcium metabolism. It is not yet known whether in addition to bile-acids and ergosterin other important stearins follow the same circulation. It is probable that still unknown important relations exist between the bile and other organs. Seyderhelm has lately demonstrated that the removal of the ovaries in the young dog with a biliary fistula results in disturbance of hemoglobin formation and in a chlorotic blood picture. In the complicated structure of the bile composition and in the utterly different fate of its individual components is seen a complexity of physiological processes which it is almost impossible to disentangle.

Mean Pressure and Arterial Hypertension.—Writing in the *Bulletin de l'Académie de Médecine* of February 17, 1931, H. Vaquez and D. M. Gomez point out that the diagnosis of arterial hypertension is today based on the measure of the extreme pressures, an arbitrary measure which cannot give any precise indication of the mode of evolution of the affection. The maximal pressure is an unsatisfactory criterion because it can represent only one brief moment of a vascular régime. Nor does the minimal pressure, being only the expression of the initial effort of the heart at the beginning of ventricular emptying, indicate in any way the work which the heart must do during this act. The force by virtue of which the blood circulates through the organs being the sum of these successive pressures, it is their mean which it is important to know, for it alone furnishes an idea of the work the heart accomplishes in the arterial system. The true mean pressure is that which a constant arterial régime would have in order to secure during a given time a given flow of blood. In a normal subject whose maximum is 150 mm. Hg. and whose minimum pressure is 60 mm., the mean pressure is about 90 mm., 100 at most, at the age of 40-50. Pachon observed in 1921 that the greatest oscillation in the manometer, which he calls the manometric index, coincides with the mean pressure. It is certain that there are numbers of subjects whose affection is revealed only by their mean pressure. Thus, in an illustrative case in a young man whose heart was greatly hypertrophied radioscopically, the extremes of pressure were normal, while the mean was 130 mm. Hg., 40 mm. higher than it should have been. Theoretically there is no comparison between the current method and the method of the mean arterial pressure. The former represents only a fleeting moment, the latter is the expression of the continuous effort imposed upon the heart. A moderate but permanent [illegible]n of the mean pressure will more easily provoke hypertrophy of the heart than will a systolic hypertension. It is probable that the elevation of the mean pressure is the initial stage of hypertension. We scarcely know hypertrophy today until it has become a confirmed and permanent disease. The idea of the mean pressure will permit an early diagnosis of the disease before its objective and subjective signs are visible. While its measurement is delicate, it is easy and can be made accessible to all.

The Medical Treatment of Chronic Arthritis.—In an article in the *British Medical Journal,* March 7, 1931, i, 3661, N. Mutch endeavors to provide a guide to the formidable array of drugs (more than 100 substances and preparations of published composition) employed to combat chronic arthritis. He first considers the treatment of rheumatism under four headings: (1) The removal of foci of infection and the intelligent use of antiseptics, such as ichthyol, salicylates, salol, or guaiacol carbonate, and toxin fixation by the use of an insoluble absorbent—kaolin or charcoal. (2) The local treatment, apart from orthopedic methods, which attempts to improve the circulation of the affected parts by the use of radiant heat, steam, hot wax, and medical diathermy, which are invaluable when correctly applied. (3) Raising the general resistance by healthy surroundings, ultraviolet light, a richly vitaminous diet (vitamins A and D being particularly important), and non-specific reactive therapy. (4) Raising the specific resistance by the use of autogenous vaccines. Mutch then tabulates the various groups of drugs, giving the numerous members of each. (1) The aspirin group. The sale of 1,000 tons of this drug annually in England bears remarkable testimony to its utility. Its power of relieving pain seems almost specific, being far greater than that of sodium salicylate. (2) The antipyrine group. These are simple analgesis drugs with an admittedly central action. (3) Sulphur. This substance has received wide sanction over a long number of years. It is a detoxicating agent with no systemic effects thus far observed. (4) The iodine group, the clinical value of which is undoubtedly limited in scope. It may help the rheumatic patient by stimulating a defective thyroid gland and normalizing its secretion. By the local accumulation of iodine near a focus of infection, the drug may exert a uniform action the whole day through. (5) Radioactive substances. Radium chloride may be safely given by mouth in doses of 1/100,000 mg. several times daily for a number of weeks. It is absorbed rapidly, permeates the tissues freely, and after storage in the liver is eliminated through the bowel wall. Other radioactive substances also available are thorium and mesothorium. (6) Thiosinamine, which it would appear rash to use unless the patient can be kept under close observation. (7) Cinchophen, which has little justification for use if pain can be con-

trolled in other ways. (8) The hexamine group. The clinical effects of these preparations are quite imperceptible. In making a therapeutic plan, a critical survey of every organ and system in the body is essential. It is well to keep in mind the scheme of treatment outlined in the early part of the paper and to decide where the chief effort should be centered and then medicinal agents can be selected with confidence.

Acidosis from the Clinician's Point of View.—Leonard Findlay is of the opinion that there has been much loose thinking and talking on the subject of acidosis. To raise this condition to the position of a clinical entity is as much a retrograde step as it would be to classify diseases according to the presence or absence of fever It must be recognized at the start that the circulation of free acids in the blood is impossible in life, with the exception of carbon dioxide, which is the only free acid found in the blood What we understand as acidosis is a metabolic disturbance with the tendency to the production of an acid state of the blood if matters were allowed to go on uncontrolled. However, a low carbon dioxide blood content does not always indicate a tendency to the production of a more acid state of the blood. It depends entirely on how the diminished carbon dioxide content is produced. If it is the result of forced respiration, either voluntary or due to high altitude, the primary change is a loss of normal acid with a tendency to the production of alkalosis. In this type of alkalosis as well as in that found in pyloric stenosis, acetonuria occurs. This should give the death blow to the current opinion that the presence of acetonuria always indicates acidosis. The complex mechanism of the body which regulates the acid-base balance involves not only the so-called "buffer" action of the blood, but also the excretory functions of the lungs and kidneys. Hence the importance of the health of these organs. An example of acidosis in disease is that found in fatal cases of gastroenteritis; it is due to the loss of fluid by vomiting and diarrhea. The rational treatment is to replace the fluids and to hinder the formation of acetone bodies by the administration of water, salts, and glucose, and this should be done at all costs. Another example of acidosis is that of diabetes, which is due to the incomplete burning of fats with the production of ketones, and also to the washing out of fixed alkalies in consequence of diuresis. In acidosis artificially produced by the administration of calcium chloride or ammonium chloride, or in that produced by starvation, or by disturbing the balance of fat and carbohydrate in the diet, no symptoms are apparent, and within a day or two the blood becomes modified. This demonstrates the remarkable power of the body to accommodate itself to new conditions as long as the tissues are healthy, and also that the symptoms of acidosis are not so much due to any peculiar pathological process as to the inability of the tissues to exert their inherent regulating mechanism.—*British Medical Journal*, March 14, 1931, i, 3662.

The Etiology and Therapy of Gastric Ulcer.—According to Paul Siebert, the question of the treatment of gastric ulcer stands or falls in the last analysis with our view of its genesis. After reviewing the various theories of its origin, the author takes his stand with Büchner and Knotzke that the earliest stage of the ulcer consists of a superficial fibrous eschar of the upper layers of the mucous membrane. It has been demonstrated that the necrosis of the mucosa comes about independently of the stoppage of vessels, and that vascular changes are of a secondary nature. It is of special significance for the etiology that the secretion of acid gastric juice belongs exclusively to the glands of the corpus, whereas the site of ulcers is almost exclusively in sections that have nothing to do with secretion, namely the cardiac portion, the main part of the lesser curvature with the portions of the anterior and posterior walls immediately adjoining it, and the pyloric canal. Büchner has shown that ulcer formation is limited to zones of the mucous membrane that lie in the region of the action of the gastric juice but do not participate in its formation. This raises the question whether an organ such as the stomach can be digested by its own secretion. In health this can surely not occur, but it is conceivable that in the correlation of gastric juice to gastric wall the juice may under pathologic conditions exert an increased activity against the wall, either from increased secretion of a highly concentrated juice or from failure of defenses in the wall. By administering histamine to rats the author and his associates have demonstrated a parallelism between the resultant ulcers and the strength of secretion of gastric juice. The greater the possibility of the action of acid juice on the gastric mucosa, the larger was the number of ulcers produced. They developed in the region of such action, but not in the zone of its formation. These new discoveries must be taken into account in determining the treatment. A diet should be chosen which does not irritate the stomach in either its secretions or its mechanics. It matters little which of the many ulcer diets is given, provided this condition is fulfilled. Atropine or belladonna seems indispensable. Siphonage is likewise an essential part of treatment, having a marked effect upon the fasting gastric secretion. After meals the acid may be neutralized by administration of telluric alkalies (magnesia usta, calcium carbonate, or magnesia perhydrolate. Sodium bicarbonate should be discarded unconditionally from treatment of ulcer, since its secondary effect of increasing acid has been established beyond a doubt.—*Deutsche medizinische Wochenschrift*, March 6, 1931.

LEGAL

LIBEL—PUBLICATION ESTABLISHED BY DICTATION TO STENOGRAPHER

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Our Court of Appeals recently had occasion to consider a very interesting question involved in an action for libel. The case came before the Court of Appeals purely as a question of law upon the following state of facts:

The plaintiff brought an action against the defendant in which it was alleged that the defendant composed a libelous letter wherein he stated: "If you (referring to plaintiff) do not appear in this office Monday with the money and notes, my attorney will be instructed to go to the District Attorney's office to procure a warrant for your arrest and X will be notified that this money and notes were given you upon false representation." The plaintiff alleged that the defendant thereby intended to charge the plaintiff with larceny; that he intentionally and maliciously published such matter by dictating it and by causing it to be read and transcribed by a stenographer. It was further alleged that the defendant mailed the letter to the plaintiff and that the statements were malicious, libelous and untrue.

The defendant then made a motion to dismiss the complaint upon the ground that the dictation of this letter by the defendant to his stenographer was not a publication of the letter and, hence, one of the necessary elements in a libel case was lacking.

The case in this State presented a novel question. Although the question had been before the Courts of England and in various States in this country, the higher Courts of our State had never passed upon this question as affecting an individual defendant. Over forty years ago in England it was held that the dictation of a letter to a stenographer does constitute a publication so as to render the dictator of such letter answerable in money damages to the addressee, provided, of course, that the letter is of a defamatory nature. In the English case the Court said:

"Certainly it is shewing it to a third person; . . . I cannot, therefore, feel any doubt that, if the writer of a letter shews it to any person other than the person to whom it is written, he publishes it. If he wishes not to publish it, he must, so far as he possibly can, keep it to himself, or he must send it himself straight to the person to whom it is written. There was, therefore, in this case a publication to the type-writer."

Further on, the Court took occasion to say:

"I do not think that the necessities or the luxuries of business can alter the law of England. If a merchant wishes to write a letter containing defamatory matter, and to keep a copy of the letter, he had better make the copy himself."

One of the Justices concurring stated:

"It is said that our decision will cause great inconvenience in merchants' offices and will work great hardship. . . . I think the answer to this is very simple. I have never yet heard that it is in the usual course of a merchant's business to write letters containing defamatory statements. If a merchant has occasion to write such a letter he must write it himself, and make a copy of it himself, or he must take the consequences."

The Court of Appeals held on the facts here recited that the English rule should be followed, and that the complaint sufficiently charged publication. The decision of the Court of Appeals was non-unanimous, four judges holding that publication was established and three judges holding that upon the facts the libel action cold not be sustained since, in the opinion of the dissenting minority, there was no publication of the libel. In the majority opinion the Court said:

"In the law of defamation, publication is a term of art. A defamatory writing is not published if it is read by no one but the one defamed. Published it is, however, as soon as read by any one else. The reader may be a telegraph operator, or the compositor in a printing house, or the copyist who reproduces a longhand draft. The legal consequence is not altered where the symbols reproduced or interpreted are the notes of a stenographer. Publication there still is as a result of the dictation, at least where the notes have been examined or transcribed. Enough that a writing defamatory in content has been read and understood at the behest of the defamer.

"The argument is made that the wrong in such a case of slander and not libel. 'It is difficult to see how A can publish to B a document which is written by B himself' (citing from textbook). The criticism would be just if B were the author of the document, or wrote it of his own motion. The point is dulled when we remember that in noting and transcribing he does the bidding of the defamer, who has used him as an instrument to give existence to the writing. Very often a stenographer does not grasp the meaning of dictated words till the dictation is over and the symbols have been read. This is particularly

likely to be the case where a defamatory charge is made equivocally or with evasive innuendoes. The author who directs his copyist to read, has displayed the writing to the reader as truly and effectively as if he had copied it himself . . .

"The soundness of a conclusion may not infrequently be tested by its consequences. Let us assume a case where words, unaccompanied by special damage, are libelous if written, but are not slanderous per se. Let us assume that the defamer has a grudge that will be served by defaming his victim in the thought of a particular person. Let us assume that this person is also his stenographer. With that mind he dictates the defamatory words and instructs the stenographer to preserve and read what has been written. By hypothesis, the one defamed is without a remedy for slander. By hypothesis, too, a writing has been created at the instance of the defamer and lodged in the custody of the very person whose mind was to be poisoned. The outrage is without redress if the libel is not published when written out and read."

On principle, it would seem that the majority opinion is correct, and indeed it represents the great weight of authority in those Courts where the question has already been presented for decision.

CLAIMED NEGLIGENT TREATMENT OF OSTEOMYELITIS

In this case the plaintiff was a physician and surgeon who specialized in oral surgery and in addition does general dental work. A patient called at his office complaining of pain in his jaw stating that while at work in his office a fellow-employee had in some way bumped his head against his (the patient's) jaw.

The doctor suspected osteomyelitis of the mandible and so took a test of his blood and urine. The laboratory reports were negative. *X*-rays taken of the teeth and jaws showed no fracture and no diseased condition. The patient returned to the doctor on several successive occasions, each time complaining of pain. The doctor decided that a condition of osteomyelitis was probably present and placed him in a hospital under observation, and as the symptoms observed there confirmed the tentative diagnosis, he decided to operate. Under ether anesthesia an incision was made along the lower border of the left mandible to the left of the median line down to the periosteum. The doctor found an area of osteomyelitis about 1½ c m. in diameter which he carefully removed. He then put in one catgut suture and inserted an iodoform gauze drain. The doctor then made another incision on the other side of the mandible down to the bone, but could not definitely locate any pus. This was similarly dressed but not sutured. The patient's condition improved and he left the hospital in a few days, shortly after which the second bicuspid tooth on the upper right side was removed by an assistant of the plaintiff doctor. Two days later the doctor saw the man and this was the last time. At that time there was a swollen area of the mandible and the wounds were not healed completely, but needed further dressings. The patient was told to return but failed to.

Subsequently the doctor sued for his bill and the patient interposed a counterclaim of malpractice claiming that the treatments had been negligent and unskillful throughout. The case was duly brought on for trial. The defendant was unable to support his charges of malpractice and the doctor obtained a judgment for his bill and a dismissal of the counterclaim for damages.

CLAIMED NEGLIGENT OPERATION ON EYE, CAUSING BLINDNESS

The defendant in this case was a physician, specializing in eye cases. The plaintiff, an elderly colored lady, called at his office complaining that she could not see with her right eye, and blamed this defect of vision on an operation performed by the doctor several years before. That operation had been for the removal of the right lachrymal gland, and at that time the patient's recovery had been uneventful.

The doctor examined the patient's eyes and found no condition which could be traceable to the earlier operation. He found the right [illegible] be completely blind, but healthy, the [illegible] ing due to a cataract. He also observed a [illegible] forming near the left eye. The only treatment performed by the doctor for the patient at this time was to prescribe for a pair of glasses for her.

The doctor heard nothing more from this woman, until some time later a summons was served upon him. The attorney for this woman did not serve a complaint, but attempted to negotiate a settlement with your counsel. The circumstances, of course, indicated that the suit was a mere strike, and your counsel refused to countenance any negotiations for settlement, and obtained a dismissal of the entire matter by rea[illegible] the failure of plaintiff's attorney to [illegible] plaint within the time prescribed [illegible]

CLAIMED NEGLIGENT TREATMENT OF INFECTED FINGER

In this case a young woman called at the office of a general medical practitioner complaining of an injury to the end of her finger, caused by the puncture of a pin. The doctor examined it and found a slight infection but decided it was not ready to open, so advised her to apply wet dressings of hot boric acid solution and to return to him in twenty-four hours. The patient, however, waited for a week before returning, when she told the doctor that during the intervening time she had used an ointment, hoping that the abscess would open spontaneously, but instead it had become progressively worse. Therefore, she had returned to the doctor to have him open it. The doctor discovered the finger to have become extremely swollen and tender, with evidence of osteomyelitis of the distal phalanx. He made a semicircular incision of the tip of the distal phalanx under local anaesthesia of novocaine, released the pus and inserted a drain. He advised continuous wet dressings of hot boric acid solution. He treated the patient daily for about a month and then on alternate days for two weeks additional. Each time he changed the dressings, he removed whatever necrotic tissue and pus were present, and bathed it with peroxide or Dobel's solution. He also administered Sunray treatments on the last few occasions. The wound improved considerably and when he last treated her, it was clear from pus and the finger was normal in size and free from pain. The edges of the wound did not unite, and the doctor advised the patient on her last visit that he would have to scrape the edges in order that the wound might close. The patient never appeared at the doctor's office for that purpose. The doctor sent his bill some time later, which was not paid. Thereafter the doctor instituted suit, through his attorneys, for the collection of this bill. A counterclaim was interposed by the defendant, setting up that the plaintiff doctor was guilty of malpractice.

Your society's counsel became associated in the case to defend the doctor against the counterclaim. The defendant specified the claim of malpractice to be that the doctor's improper treatment failed to cure her condition, left her with a disfigurement, and subjected her to the necessity of a skin graft operation.

The defendant's attorney attempted to delay the suit wherever possible, but the case was brought on to trial and the counterclaim of malpractice dismissed at the same time that judgment was rendered in favor of the doctor for his bill.

ALLEGED NEGLIGENCE IN BREAKING OF NEEDLE AND NOT REMOVING SAME

The defendant doctor in this case was called to treat a four-year-old boy for whooping cough. As part of his treatment the doctor gave two injections of pertussin vaccine into the arm of the patient. He carefully instructed the mother to hold the child firmly. The first injection was uneventful, but during the second injection, the mother failed to hold the boy securely, according to instructions, and the child, while the needle was being inserted into his arm in a slanting position, swung around suddenly causing the needle to break.

The doctor immediately attempted to remove the broken portion of the needle and succeeded in grasping the needle, but the child became extremely unruly, and could not be governed sufficiently to allow the doctor to remove the needle, and it slipped under the skin.

The doctor then decided that the broken needle could not be removed without anesthesia, and instructed the child's mother to take him immediately to a hospital, giving her a letter arranging for the removal of this needle. The doctor was informed that the child was placed in the hospital and remained there a few days while *x*-rays were being taken. At the end of that time the woman took the child home from the hospital against instructions. The needle apparently was never removed by anyone, but caused the child no discomfort.

Suit was instituted against the doctor charging him with malpractice in his treatment of this child. The case was noticed for trial and when it was reached for trial the plaintiff's attorney failed to appear to try the same. Upon motion of the defendant's attorney the complaint was dismissed. The default of the plaintiff, however, was opened by a court order and the action was then tried before a Judge and Jury. The plaintiff contended that the defendant was negligent in permitting the needle to break and that he was negligent in failing to appear at the hospital to attend the child. At the close of all the evidence the defendant's attorney moved for a dismissal of the complaint which was granted.

NEWS NOTES

REPORT OF THE COUNCILOR OF THE SECOND DISTRICT BRANCH

To the House of Delegates:

During the past year the Second District Branch has grown in numbers and activities. The membership now totals 3,079. In Suffolk County the activities of the Public Health Committee has upon its program 1. Measles prevention, 2. Cancer elimination, 3. Tuberculosis prevention, especially a continuation of the study of the incidence of Tuberculosis among the families and children of patients in the infective stage of the disease. The Medical Economics Committee has shown concrete results from conferences with the Commissioner of Welfare and the Superintendents of the Hospitals in the County. The County Health Department, (now over two years old) was the first organized by the action of a County Medical Society. Its satisfactory service and organization have attracted the attention of neighboring and distant States. It now has a veterinary division, the first of its kind to be established in the United States under a County Board of Health and therefore medically controlled. Investigations of diseases of animals which can be conveyed to man are being conducted, notably streptococcus mastitis, contagious abortion of cattle, and rabies in dogs. The Monthly News Letter is of great value in communicating to physicians and the public the activities of the Society, health conditions in the County, and all types of welfare work. Suffolk is proud to have furnished President Ross to the State Society and they are even more gratified to learn how widely he has reached the various County Societies in their meetings, how his counsels have been sought by the Governor, the Health Commissioner, the Commissioner of Labor and various Welfare organizations, and how he has advanced the cordiality of the relations of our Profession with the Public.

In Nassau County the outstanding accomplishment of the year has been the voter's authorization of a County Hospital, for which the County Medical Society worked with vigor and devotion rare in Medical Society history. Plans for the Hospital are drawn, and its completion will be a great and much needed addition to the medical facilities of this attractive thriving section. The work in Diphtheria prevention has advanced this year even farther than before and the latest reports of incidence of the disease show definitely the magnificent accomplishment of Nassau County Society. The meetings this year have presented programs of extraordinary interest and the attendance averages over sixty per cent. We wonder how many County Societies having monthly meetings can show this?

In Queens County the new Society Building has helped to promote activities and to evolve new responsibilities. Necessarily dues were increased. Books in the Library are accumulating. There are now over ten thousand volumes. However, the library is not yet functioning due to delayed equipment and lack of necessary funds. The Committees have been very active, notably Public Health and Public Relations, and Graduate Education (lectures, exhibitions, and special public meetings). The Queensboro Tuberculosis and Health Association have given financial and other cooperation in these activities. Altogether Queens is in a busy, earnest, constructive stage of its existence and will win a high place among the County Societies of the Nation.

In Kings County the works started in previous years have been continued with growth and increase in detail. Graduate Education courses have been given as before and twenty Friday afternoon lectures have been given. The programs in Diphtheria Prevention, examinations of children entering school for the first time, and the Health Promotion work in Continuation Schools have been carried forward. Under the auspices of the Committee on Medical Economics four well attended open meetings or forums have been held and many items have been discussed in such a manner as to aid the Committee in its work. Two thousand inquiries regarding physicians, medical procedures, institutions, charlatanism and other things have been received from laymen and physicians and have been answered.

One of the outstanding features of the year in Kings and Queens Counties has been the formation of the Five-County Society Coordinating Committee of the Counties (or Boroughs) making up the City of New York. Public relations and other matters which can best be forwarded by co-ordinated action of all the County Societies in the City will be considered and the Committee reports will be submitted to the various Societies for ratification or modification. It is hoped that in some manner it can be represented on the State Society Committee on Public Relations, so that its activities may add to the accomplishments of the State Committee and that it may look for corroborative helpful action by the State Committee.

Kings, Queens, Nassau, and Suffolk publish monthly Bulletins which every Doctor in the State can read with profit.

CHARLES H. GOODRICH, *Councilor*

May 1, 1931.

COMMITTEE ON PUBLIC RELATIONS

A meeting of the Committee on Public Relations was held in the Albany office on Thursday, April 23, 1931. Those present were Drs. Sadlier, Johnson, Mitchell, Hambrook, Ross and Lawrence.

In the absence of Dr. Ross, Dr. Sadlier reported that during the month he had sat with the Five-County Coordinating Committee of Greater New York, and read certain interesting excerpts from the minutes of that meeting; among them the steps the committee has taken to inform itself and its counties upon the city's program for the erection of eight health centers. One of these centers has been completed and is in operation in the Bronx. Sites for others have been chosen and are to be erected as promptly as possible. They will cost about $250,000.00 apiece and will be developed as the headquarters for all public health activities in their communities. Second, that a program for the May-day round-up was discussed and adopted. Kings and Queens Counties have been taking part in this May-day round-up for the last several years and have been following it up by stimulating the examination of school children by the individual physicians. Last year it was reported that about 47% of the children entering school in Kings County were examined by private physicians and 54% in Queens County. The Coordinating Committee meets monthly and is finding a great deal of work to do. Much of it is along the lines of public relations.

It was proposed that a sub-committee, including Dr. Sadlier as chairman of the State Committee on Public Relations, should wait upon Mayor Walker, seeking a change in the policy of the city hospitals with regard to compensating physicians for the work they do on city patients. Dr. Mitchell suggested that this committee give to the Five-County Coordinating Committee such information as we have gathered through our investigation of the practice of hospitals up-State in relation to physicians and surgeons engaging in compensation work.

The discussion having drifted toward the difficulties that attend the physician in developing a practice, brought from Dr. Hambrook the remark that recently he had been invited by the principal of the Troy Day School to address the boys on the general subject of "Medicine as a Profession." The school has had representatives of several professions address the boys. At the close of Dr. Hambrook's address, one boy asked how much the physicians are paid for their work in the hospitals.

Dr. Ross, having come in at this point, reported upon the first meetings of the Governor's Special Committee to investigate medical and hospital problems in connection with the Workmen's Compensation Law's operation. The workmen were heard and they made it clear in all of their testimony that they have no grievance against the medical profession as such; that while there might be particular instances where they may have felt they did not receive proper care, such instances were few and isolated. On the other hand, they indicated that they have a serious grievance with the carriers and with representatives of the State Department of Labor. They gave numerous instances, citing exact data, where they consider themselves unjustly treated. Dr. Ross feels that the investigations of the committee are going to be highly worth while and their reports very illuminating and instructive. He recommends that the Public Relations Committee make an effort to keep in touch with the work of the Investigating Committee and, when possible, attend hearings. Governor Roosevelt, in announcing the committee, said that the investigation he had in mind related rather to "adequacy of the medical treatment of injured workmen" than to the adjustment of claims. The committee will take up these subjects: (1) The payment of adequate rates to the hospitals for bed and clinic care when handling workmen's compensation cases; (2) Suggestions as to the elimination of causes for delay in payment of hospital bills; (3) The subject of hospital record keeping in workmen's compensation cases; (4) Study of medical and hospital treatment and payment therefor in certain cases which have regularly eluded payment of medical and hospital costs in the past, such as third-party actions, non-insured employer cases and injuries reported to the Department of Labor either by employer or employee; (5) Standards of medical and hospital treatment in workmen's compensation cases.

The personnel of the committee follows:

Miss Frances Perkins.....Industrial Commissioner
Dr. Charles H. Johnson.Commissioner of Social Welfare
Dr. Frederick W. Parsons,
Commissioner of Mental Hygiene
Hon. George S. Van Schaick.....Rochester
Howard S. Gans, Lawyer.....New York City
Henry Fisher.....United Hospital Fund
Vincent Astor .....New York City
Dr. William H. Ross.....State Medical Society
Max Meyer.....Member Industrial Council
Dr. Adrian VanS. Lambert.....New York City
Dr. James Alexander Miller.....New York City
Marshall Field .....New York City
James Speyer .....New York City
Charles Deckleman.....Travelers Insurance Co.
Maxwell Wheeler.....President, Associated Industries

Hon. Howard S. Cullman.....New York City
Thomas J. Curtis.....N. Y. State Federation of Labor
Dr. S. S. Goldwater.....New York City
Dr. Edward A. King.....New York City
O. G. Browne.....New York City
Dr. Geo. F. Chandler.....State Medical Society

Dr. Ross next reported on his visit to Otsego County and Cooperstown. He visited with the Otsego County Society on Tuesday evening and made inquiry concerning the reaction to the Cooperstown program. He was surprised to find that there is practically no opposition to it; in fact, few seemed to have any interest whatever in it. After the adjournment of the meeting he went to the Cooperstown Hospital as a guest of some of the doctors who were in attendance at the meeting. The guild which they created had two hundred members on January 15th, and on March 15th the cost of conducting the guild was only about two-thirds of the share of the five thousand dollars that would be allotted to that period of time. These two hundred members are mostly from that group of people who would be able to pay $25.00 a year, but would find it difficult to pay the regular hospital charges in case they were ill. Some few of the members are having their dues paid by persons outside the guild who are interested in their welfare. There are several of the members in the hospital now. Cooperation between the hospital physicians and the one physician residing in Cooperstown who is not a member of the hospital staff, seems free and cordial. The school work of the city is done by a member of the staff and his compensation is collected by the hospital. A member of the staff is also the health officer and his compensation, likewise, is collected by the hospital. It seemed to appear from the report that the hospital authorities had changed their plans somewhat with regard to the membership, and it was suggested that the president write to the hospital, asking whether they had deliberately changed their program so as to admit to membership only those persons who might be considered self supporting and, yet, not able to pay the regular hospital rates in the event that they were ill. (See page 642.)

Dr. Hambrook pointed out that if people were permitted to pay the membership fees of others unable to support themselves, the city welfare departments might use a similar plan in caring for their wards at a great saving to the city.

Dr. Mitchell stated that he felt it would be much wiser to attempt to discuss with the County Society officers the desirability of exercising great care in selecting committees, rather than to write a letter. The committee concurred.

Dr. Sadlier read a proposed letter to be written to the deans of the medical schools, asking that a greater interest be taken in acquainting the medical students with our new public welfare law. The letter was approved. The committee also instructed the chairman to prepare and write a letter to the chairmen of the County Society Public Relations Committees, urging their interest in developing public sentiment against the recognition by the legislature of various cults.

It was also decided that the chairmen of the Public Relations Committees of the counties from which surveys have been received, should be asked to report upon the activities of their committees since submitting the surveys, and that all of the committees should be urged to participate in the May-day round-up exercises in a manner similar to that found so advantageous and profitable by the counties in Greater New York.

The committee then adjourned to luncheon, where they had invited as guest Mr. O'Hanlon, secretary of the New York State Federation of Labor. They conferred with him upon the subjects in which our organizations might be expected to have a mutual interest. They touched upon a number of subjects and it was quite apparent that another conference should be arranged to which Mr. O'Hanlon would invite members of his organization. He stated that at their next annual conference, which will be held in August in Syracuse, he will ask the society to appoint a live committee on medical relations, and it was then decided that we would arrange for a joint meeting some time in October or November.

The committee adjourned to meet again on Thursday, May 21st, in Albany.

J. S. LAWRENCE,
Executive Officer.

ALBANY COUNTY

The March meeting of the Medical Society of the County of Albany was held at our regularly appointed meeting place, the Aditorium of the Albany College of Pharmacy, on March 30, 1931. There were present about 150, including physicians from Schenectady, Troy and adjoining counties.

The meeting was opened by the President, Dr. Charles K. Winne, Jr. Following the reading of the minutes of the previous meeting, Dr. Arthur J. Bedell, Chairman of the Program Committee, announced that the next regular meeting would be held at the Memorial Hospital, and that the Scientific Program would be arranged by the Hospital Staff.

Dr. James F. Rooney, Chairman of a Special Committee, discussed the present bills pending before the State Legislature.

Dr. Henry L. K. Shaw, Chairman of a Special Committee, read resolutions on the death of our late member, Dr. James P. Boyd, a former President of this Society, and at one time Professor of Obstetrics, Gynecology and Diseases of Children at the Albany Medical College. It was pointed out that Dr. Boyd's father was a physician who began the practice of medicine in Albany in 1825 and continued to practice medicine for some fifty-five years. Dr. James P. Boyd, Jr., became a member of our Society in 1873. In this connection it is an interesting fact that a Dr. James Peter Boyd has been on the medical roster of Albany from 1825 until 1931, a period of more than one hundred years.

The applications of F. Constance Stewart and James L. Spencer were presented and both unanimously elected to membership.

A communication was received from the Fort Orange Council, Boy Scouts of America, acknowledging receipt of our check for the first aid medal provided by the County Society. This medal is awarded each year to the winner of the First Aid Contest conducted by a special committee appointed by the Society.

The Scientific Program consisted of a very scholarly and interesting address by Dr. F. d'Herelle, Professor of Bacteriology, Yale University School of Medicine, who spoke on the subject of Bacteriophage and Recovery from Infectious Diseases.

The discussion was opened by Dr. Augustus Wadsworth, Director of Laboratories, New York State Department of Health and contined by Dr. Arthur W. Wright, Director of the Bender Laboratory of Albany. Further discussion was continued by Doctors Rooney, Neuman and Corning.

Following a rising vote of thanks to Dr. d'Herelle, the meeting adjourned at 10:55 P.M.

HOMER L. NELMS, *Secretary.*

The April meeting of the Medical Society of the County of Albany was held at the Memorial Hospital, Albany, N. Y., on Tuesday evening, April 14, 1931. The President, Dr. Charles K. Winne, Jr., presided.

Dr. Arthur J. Bedell, Chairman of the Program Committee, announced that the May meeting would be held at the Laboratory of the New York State Department of Health, and that the program would be furnished by the Laboratory Staff.

Dr. A. C. Worth presented resolutions on the death of our late member, Dr. Harold Duncan Cochrane, who died in Albany, April 7, 1931. By direction of the Society these resolutions were accepted and ordered spread upon our minutes and a copy sent to the family of the deceased.

The Transfer of Dr. Frederick L. Parry from the Oneida County Society to the Albany County Society was announced.

The Scientific Program consisted of the following interesting papers and case histories presented by members of the Staff of the Memorial Hospital:

Recurrent Dislocation of the Shoulder—Operative Treatment. Dr. Philip L. Forster, Albany, N. Y.

The Aschheim-Zondek Test for Pregnancy—Preliminary Report. Dr. Harold A Peck and Dr. Arthur W. Wright.

Pneumo-peritoneum—Case Report. Dr. Edgar A. Vander Veer.

Through the courtesy of Mr. T. T. Murray, Superintendent of the Hospital, a luncheon was served following the meeting.

HOMER L. NELMS, *Secretary.*

THE DAILY PRESS

BIRTH CONTROL

The *New York Herald Tribune* of April 22, contains the following editorial on the relation of physicians to birth control:

"The action of the New York Academy of Medicine indorsing birth-control clinics, urging education of the public in sex matters by the medical profession, and suggesting modification of existing state and Federal legislation on birth control has only just been made public, but in fact it antedates the similar statements made by the Lambeth Conference of Anglican Bishops and the Federal Council of the Churches of Christ in America.

"The academy is an old and respected institution devoted largely to medical research; its conclusions are the fruit of long and mature study, and will carry weight with the medical profession throughout the country and with laymen. The recommendation that the law be modified dates back ten years; the other proposals, first made by a subcommittee of the important Public Health Relations Committee, were indorsed by the council of the academy more than a year ago. But the medical profession is notoriously conservative and fearful of publicity; it acts slowly, and it is still more slow to take the public into its confidence.

"However, that is one of the reasons why the public has faith to follow when such a body as the academy takes the lead. When the academy says that recent research in technique demands recognition by the profession, the public will believe it, and will not understand it if individual members of the profession fail to accept the responsibility for educating the public which the academy assigns it. The action of the academy should go far to fortify individual physicians in a position which some have been hesitant to assume; and it should go far to encourage the efforts to modify the medieval legislation, both state and Federal, which still lingers on the statute books."

HE'S A TOUCH OLD BIRD AND HAS WEATHERED A LOT OF DEPRESSIONS

From the New York Herald-Tribune, April 23, 1931.

THE SCIENTIFIC HUNCH

The word "hunch," used in the sense of premonition, is classed as a colloquialism by some lexicographers, and ignored by others; but it fills a real want in the English language. The New York *Herald Tribune* of March 30, discusses the scientific value of the hunch as follows:

"How 200 scientists, dealers in the mathematical, the exact and the absolute, had employed the layman's lowly hunch to awaken their inventiveness was revealed today.

"The findings were made public in a questionnaire released by the American Chemical Society, which begins its eighty-first annual meeting here tomorrow. The canvass was conducted by Professor R. A. Baker, of the College of the City of New York, and Dr. Washington Platt, of Syracuse. It was made for the department of chemical education.

"The hunch," says the report, "follows a long period of study, 'but comes into consciousness when we are not consciously working on the problem. It is a process of creative thought.'

"Such a hunch came to one scientist 'while dodging automobiles across Park Row and across Broadway in New York.' Another, an improvement in oil pipeline coils, was discovered one Sunday in church. 'The correct principle,' says this scientist, 'came like a flash as the preacher was announcing the text. Strange to say, I have always remembered the text and the sermon.' But it was not learned what the text was.

"After the hunch, scientists cash in by painstaking tests. Many report that they try to create hunch conditions, some even in dreams. One of these keeps a handkerchief at hand to tie around his arm so as to remind him in the morning of his dream."

APHORISMS FOR DOCTORS

Physicians may often use selected aphorisms in their writings in order to enhance the appearance of erudition on part of the authors, and to afford breathing spells on part of the readers. During the past year or two the NEW YORK STATE JOURNAL OF MEDICINE has used nearly every one of the following aphorisms compiled by Glenn Compton, and printed in the *New York Herald Tribune* of May first, and will probably use them over again next year:

"The rolling stone collects no moss;
Gambling throws you for a loss;
Nor borrower nor lender be;
A stitch in time saves two or three,
Or six or eight or maybe nine;
In bottles old put no new wine;
Play not with fire, for it will burn;
The road is long that does not turn;
Handsome is as handsome does;
There's nothing new, there never was;
Cross no bridges in advance;
The highest bliss is ignorance;
Put something by for rainy days;
Let not thy head be turned by praise;
The child is father to the man;
It can be done, you know it can;
Burn not the candle at both ends;
For all your sins make full amends;
Spare the rod and spoil the child;
Be not by siren's lures beguiled;
Great oaks from little acorns grow;
Man wants but little here below;
A barking canine never bites;
A brave man down gets up and fights;
The dead goose lays no golden egg;
A hole that's round fits no square peg;
As you sow so shall you reap;
Always look before you leap;
A friend in need's a friend indeed;
Of the morrow take no heed;
'Tis an ill wind blows no good;
Great men are misunderstood;
Rome was built not in a day;
While the sun shines make thee hay;
Enchantment is by distance lent;
Rich men seldom are content;
To thy proper self be true;
Credit give where it is due;
For no man wait the tide and time,
And here's the reason for my rhyme:
A little nonsense now and then
Is relished by the best of men."

TRAINING DELINQUENT YOUTHS

The *New York Times* of April 22 contains the following editorial account of modern methods of training delinquent youth:

"In the annual report of the Society for the Reformation of Juvenile Delinquents, just published, is an account of the four methods of training used for all boys at Randall's Island. The House of Refuge there is not a place of punishment, but a school where instruction and practice bring the boys into wholesome relation with each other and with the adults in charge of them.

"Religious and common school instruction are given very much as if the boys were not committed to an institution. This is supplemented by military training, which gives the boys exercise, a smart carriage, habits of neatness and, above all, respect for discipline and an esprit de corps.

"The fourth kind of training has been found most useful to the boys in fitting them for work in the world on parole. They are taught many trades, and are permitted to use the knowledge acquired in the vocational classes when work is to be done about the buildings and grounds. Boys from the tailoring classes make the clothes of the institution. Farming and gardening students contribute to the table. The steam tug is manned by another group. Repair of paint, plaster, plumbing, steam pipes and all necessary carpentry are done by the boys. No outside mechanic has been employed for some time.

"This work is valuable, not only as it supplements class instruction, but because it gives the boys the feeling of doing something of importance for their small community."

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

A HANDBOOK ON DISEASES OF CHILDREN: including Dietetics and the Common Fevers. By BRUCE WILLIAMSON, M.D., M.R.C.P. 12mo of 290 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $3.50.

AN INTRODUCTION TO PRACTICAL BACTERIOLOGY: A Guide to Bacteriological Laboratory Work. By T. J. MACKIE, M.D., D.P.H. and J. E. MCCARTNEY, M.D., D.Sc. Third edition. 12mo of 421 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $3.50.

MODERN METHODS OF TREATMENT. By LOGAN CLENDENING, M.D. Fourth edition. Octavo of 819 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $10.00.

CANCER: Its Origin, Its Development and Its Self-Perpetuation. The therapy of operable and inoperable cancer in the light of a systemic conception of malignancy. A research. By WILLY MEYER, M.D. Octavo of 427 pages, illustrated. New York, Paul B. Hoeber, Inc., 1931. Cloth, $7.50.

CHININ IN DER ALLGEMEINPRAXIS Unter Berücksichtigung Pharmakologischer Befunde. By DR. FRITZ JOHANNESSOHN. Octavo of 232 pages, illustrated. Amsterdam, Bureau Tot Bevordering Van Het Kinine-Gebruik, 1930. Paper. (On demand, copies will be sent to medical men free of charge.)

A TEXTBOOK OF LABORATORY DIAGNOSIS with Clinical Applications for Practitioners and Students. By EDWIN E. OSGOOD, M.A., M.D., and HOWARD D. HASKINS, M.D. Octavo of 475 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $5.00.

SURGICAL CLINICS OF NORTH AMERICA. Vol. 11, No. 1. February, 1931. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, $16.00 net; paper, $12.00 net.

SELECTIONS FROM THE PAPERS AND SPEECHES OF JOHN CHALMERS DACOSTA, M.D., LL.D. Octavo of 440 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.50.

ROENTGEN INTERPRETATION: A Manual for Students and Practitioners By GEORGE W. HOLMES, M.D., and HOWARD E. RUGGLES, M.D. Fourth edition. Octavo of 339 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $5.00.

QUANTITATIVE CLINICAL CHEMISTRY. By JOHN P. PETERS, M.D., M.A., and DONALD D. VAN SLYKE, Ph.D., Sc.D. Volume 1, Interpretations. Octavo of 1264 pages, illustrated Baltimore, The Williams & Wilkins Company, 1931. Cloth, $12.00.

A HANDBOOK FOR SENIOR NURSES AND MIDWIVES. By J. K. WATSON, M.D. Second edition. 12mo of 676 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $4.00. (Oxford Medical Publications.)

PRIMARY SYPHILIS IN THE FEMALE. By THOMAS ANWYL DAVIES, M.D. Octavo of 111 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $4.00. (Oxford Medical Publications.)

THE DIET BOOK FOR DOCTOR, PATIENT AND HOUSEWIFE with specimen menus for one week and recipes. By MARGUERITE REQUA REA. 12mo of 197 pages. New York and London, Oxford University Press, 1931. Cloth, $2.75.

COAL-MINERS' NYSTAGMUS. By G. F. HAYCRAFT, M.R.C.S., L.R.C.P. 12mo of 15 pages. New York and London, Oxford University Press, 1931. Paper, 30c. (Oxford Medical Publications.)

MEDICAL CLINICS OF NORTH AMERICA. Vol. 14, No. 5 March, 1931. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, $16.00 net; paper, $12.00 net.

AIDS TO BACTERIOLOGY. By WILLIAM PARTRIDGE, F.I.C. Fifth edition. 16mo of 311 pages. New York, William Wood & Company, 1931. Cloth, $1.75. (Students' Aids Series.)

THE THEORY OF OBSTETRICS: A functional study of child-bearing based on a new definition of normal labor and on a new theory of uterine inertia. . . . By M. C. DE GARIS, M.D. Octavo of 272 pages. New York, William Wood and Company, 1931. Cloth, $5.00.

AN INTRODUCTION TO HUMAN EXPERIMENTAL PHYSIOLOGY. By F. W. LAMB, M.D. Octavo of 335 pages, illustrated. New York, Longmans, Green & Company, 1930. Cloth, $4.00.

THE LETTERS OF DR. BETTERMAN. By CHARLES ELTON BLANCHARD, M.D. Octavo of 157 pages, illustrated. Youngstown, Ohio, Medical Success Press, 1931. Paper, $1.00.

TEXTBOOK OF HUMAN EMBRYOLOGY. By CLEVELAND SYLVESTER SIMKINS, Ph.D. Octavo of 469 pages, illustrated. Philadelphia, F. A. Davis Company, 1931. Cloth, $4.50.

EASIER MOTHERHOOD: A discussion of the abolition of needless pain. By CONSTANCE L. TODD. 12mo of 199 pages. New York, The John Day Company, 1931. Cloth, $2.00.

DEEP X-RAY THERAPY IN MALIGNANT DISEASE: A report of an investigation carried out from 1924-1929 under the direction of the St. Bartholomew's Hospital Cancer Research Committee. By WALTER M. LEVITT, M.B., D.M.R.E. Octavo of 128 pages, illustrated. London, John Murray (c. 1930). Cloth, 10/6.

FACTS AND FIGURES ABOUT TUBERCULOSIS. By JESSAMINE S. WHITNEY. Quarto of 63 pages, illustrated. New York, National Tuberculosis Association, 1931. Paper, 75c; Fabrikoid, $1.00.

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. By Various Authors. (Prepared under the direction of the Medical Research Council.) Volume VI. Octavo of 538 pages. London, His Majesty's Stationery Office. 1931. Cloth, £8-8-0 a set; £1-1-0 each.

BOOK REVIEWS

A System of Clinical Medicine. Dealing with the Diagnosis, Prognosis, and Treatment of Disease for Students and Practitioners. By Thomas D. Savill, M.D. Eighth Edition. Octavo of 1019 pages, illustrated. New York, William Wood and Company, 1930. Cloth, $10.00.

This well-known and valued edition consists of approximately one thousand pages of subject matter with many and excellent illustrations.

In the plan and arrangement of this work, the author has approached the subject from the standpoint of symptomatology. He traces the symptoms and thus arrives at the cause. The order of sequence is that which is adopted in the examination of the patient. Thus, the first chapter gives the general scheme for the examination of a case; the second describes the physiognomy of disease; and the succeeding chapters deal seriatim with the symptoms and signs referable to the body and the disease which may cause those symptoms. Each chapter is divided into three unequal parts, of which Part A treats of symptoms, Part B of the physical signs, and Part C which is prefaced with a clinical classification gives a summary of the routine procedure to be adopted.

Apart from the general plan and arrangement, there are two special features. The first part of each chapter includes a complete list of symptoms and their causes. This ought to be of great benefit in helping to obtain clues to a diagnosis. The second feature consists of the italicized paragraphs in Part C, standing at the head of each section, which deal with a separate malady. They are brief clinical definitions and form "sign-posts" or guides in the process of diagnosis.

The author has adverted to certain advantages associated with the method he has adopted of approaching clinical medicine. He states that this method of diagnosis is not what is called a process of exclusion, and that it is a positive rather than a negative process. The advantages of passing in rapid review all the possible diseases which may give rise to a patient's leading symptoms are very obvious to those actively engaged in clinical work. The recognition of a clinical likeness between diseases has often led to the erection of a working hypothesis, which by subsequent research has been found to be correct. There is still another advantage which accrues, especially to the young observer, by the process of balancing evidence and comparing diseases. It not only impresses important facts upon his memory, but it constitutes one of the best possible means of training him in the habits of accurate and complete observation and of systematic and productive thought.

The medical practitioner will find this volume clear, concise, and most practical as a daily book of reference.

Henry M. Feinblatt.

Ephedrine and Related Substances. By K. K. Chen and Carl F. Schmidt. Octavo of 121 pages. Baltimore, Williams & Wilkins Company, 1930. Cloth, $2.50. (Medicine Monographs Vol. 17.)

This monograph is a review of the literature on Ephedrine and Related Substances. The authors present the subject in a concise form giving a very interesting account of this newly acquired addition to our materia medica.

The chapters on pharmacognosy and chemistry, pharmacological action, clinical applications and therapeutic uses give practically all that recent investigations have added to our knowledge of this valuable drug. F. S.

The Principles and Practice of Medicine. Originally written by the late Sir William Osler, B.T., M.D. Eleventh Edition revised by Thomas McCrae, M.D. Octavo of 1237 pages. New York and London, D. Appleton and Company, 1930. Cloth, $8.50.

This old friend of the student-days of so many of us has now reached its 11th edition (first edition 1892), and at the hands of an Osler-trained clinician, Thomas McCrae, has been continued in accustomed form and arrangement, as the Old Master would have wished.

It is not easily possible to review a practice of medicine of 1175 pages of textual matter, but as the pages turn the reviewer's attention falls on many paragraphs and items of outstanding clinical interest. Such a wealth of fact and observation! Is it to be wondered at that a copy of Osler is in the medical ward libraries of nearly every hospital!

There are new articles on Melioidosis of the Far East, Subacute Leukemia, Asbestosis, Osteitis Fibrosa Cystica, Albers-Schönberg disease, Chronic Hypoglycemia and Poisoning from Radio-active Substances. There are many alterations and additions throughout the work.

Undulant Fever is clearly presented in the light of recent studies and the *abortus* form as seen in the United States carefully described. Thrombosis of the coronary arteries is succinctly described in one paragraph on page 810; the importance of this lesion would seem to deserve extended account and a more complete discussion.

Obviously there must be omissions in a one-volume practice. The amazing thing is the amount of clinical material included between the covers of this work. Several subjects that might be added in brief are cancer of the caecum, syphilis of the adrenals, types of cardiac dyspnea, non-diabetic acidotic dyspnea of cardiac disease, paradox embolism, and the occasionally observed epidemic streptococcus sore-throat.

Frank Bethel Cross.

Diet and Disease. By George A. Harrop, Jr., M.D. Octavo of 404 pages with 80 tables. Philadelphia, P. Blakiston's Son & Co., Inc., 1930. Cloth, $4.00.

This book comprises the collected lectures to third and fourth year students on diet in disease. The first part of the book is devoted to simple introductory remarks on the principles of nutrition with a discussion of the energy requirements of the body and the physiology of the various constituents in metabolism. The author presents the dietetic portion of the book in a very interesting fashion, with a description of the ingredients of the common foodstuffs, and their place in the diet. He makes this section particularly readable by continuous reference to racial food habits. The bulk of the book is concerned with the dietetic management of the following diseases: vitamin deficiency, food allergy, undernutrition and hyperthyroidism, obesity, fever and infections, anemia, nephritis, heart disease, diabetes, epilepsy and the gastro-intestinal diseases. There is a chapter on special feeding methods, such as tube feeding, nutrient enemas and post-operative feeding. The book finally contains an appendix with a list of common foods and their food values obtained from the most recent analyses of McCance and Lawrence. The book is well written and very practical.

William S. Collens.

A MANUAL OF THE COMMON CONTAGIOUS DISEASES. By PHILIP MOEN STIMSON, A.B., M.D. Octavo of 351 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $3.75.

This handbook deals with the common contagious diseases in a clear, concise, systematic fashion. The index is excellently arranged with a view toward helping one who has little spare time to obtain precise information on any matter of practical importance in handling a case or school epidemic of any of these diseases.

The author has definitely had in mind three groups of prospective readers: medical students, physicians caring for the students in private day-schools and boarding schools, and nurses. The medical student will find here a text-book giving the most modern views of etiology, pathology, diagnosis and differential diagnosis and treatment. The second group will find very helpful the rules of quarantine for aborting epidemics in schools with a minimum loss of schooling time to the pupil. For the instruction of nurses, the Isolation Technic of Willard Parker Hospital, New York City, is given in sufficient detail for either class or private instruction.

More prominence than it really deserves is given to the author's so-called Eye-sign in Measles. The majority of the physicians attached to the staffs of contagious disease hospitals knows that it is not important and is found in every disease in which there is a conjunctivitis.

KENNETH G. JENNINGS.

CLINICAL ALLERGY particularly ASTHMA AND HAY FEVER: Mechanism and Treatment. By FRANCIS M. RACKEMANN, M.D. Octavo of 617 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $10.50.

This book fulfills admirably the purpose for which it was written: to digest the mass of literature and so correlate the new observations, but primarily to define the present day conception of the mechanism of asthma, hay fever and allied disorders, and then discuss the methods of diagnosis and treatment with the results obtained.

The first third of the book is a technical discussion of the Phenomenon of Hypersensitiveness from the physical-chemical and experimental phases. The material is not too detailed and yet includes all the important experiments. In the chapter on the "Nature and Origin of Allergy," are discussed the many problems resulting from clinical experience as well as animal experimentation.

Every phase of hay fever is clearly discussed. The charts and tracings from skin tests are interesting.

The chapters on "Asthma" are excellent. The physiology and pathology are extensively treated. The various clinical types of asthmatics with their characteristic histories are described with some differential diagnoses. The chapter on "Treatment" covers the specific and non-specific therapy.

Realizing that the entire field of allergy is still in the experimental stage, Dr. Rackemann has done much to clarify and crystallize our knowledge on the subject in this very readable and interesting book.

DOROTHEA E. CURNOW.

TEXT-BOOK FOR NURSES: Anatomy, Physiology, Surgery and Medicine. By E. W. Hey Groves, M.D., and the late J. M. Fortescue-Brickdale, M.D. Fourth Edition. Octavo of 641 pages, illustrated. London and New York, Oxford University Press, 1930. Cloth, $6.50. (Oxford Medical Publications.)

As intended to be this is a comprehensive text-book presenting the principles underlying medical and surgical treatment. The essential facts are thoroughly presented by a well written text and over two hundred illustrations, many of them in color. In this edition, a considerable number of alterations and additions have been made.

It is an excellent volume in every respect, suitable for nursing schools of the highest type.

W. E. MCCOLLOM.

THE CLINICAL INTERPRETATION OF BLOOD EXAMINATIONS. By ROBERT A. KILDUFFE, A.B., M.D. Octavo of 629 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $6.50.

Clinical examination of the blood is dealt with in this volume in thirteen chapters, including physical properties of blood, blood formation, cytology, bacteriological, serological and chemical examination of the blood. Special chapters are devoted to the various methods for the determination of changes in the behavior of red blood cells, the changes in number and type of leucocytes and to the various complement fixation tests.

An enormous amount of knowledge has been accumulated in this book, which seems to offer much needed help to those who are desirous of obtaining information without going to the original sources. It has taken considerable painstaking labor to accumulate such a vast collection of data. Although not an inspiring book to read, it will be a valuable guide for the average laboratory worker.

M. A. GOLDZIEHER.

OUTLINE IN OBSTETRICS FOR NURSES. By F. W. RICE, M.D. Octavo of 228 pages, illustrated. St. Louis, The C. V. Mosby Company, 1930. Cloth, $2.00.

The author states that this volume is not intended as a text-book. It is the accumulation of notes used in lecturing to nurses over a period of years. As an outline for a course of lectures to nurses on obstetrics the book is valuable. The students may give their entire attention to the lecture, and no time need be wasted in note taking. The illustrations are schematic, rather than exact, in order that the student may more easily grasp the principle intended to be portrayed.

The author covers obstetrics very thoroughly, and adds many things that nurses should know about the care of mother and baby. This outline, together with a standard text-book for study will give any class of nurses an excellent grasp of the subject. The book will be valuable to those who wish to give a course of lectures on this subject, and it will be an easy way to outline the course but it may not be the best plan for the lecturer. As the title indicates the field for the book is rather limited.

W. S. S.

A PRIMER FOR DIABETIC PATIENTS. By RUSSELL M. WILDER, M.D. 4th Edition. 12mo of 138 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1930. Cloth, $1.50.

This edition is of about the same size as the preceding ones and is meant for the use of the physician and of the patient who is under the care of a physician. In planning the diet prescriptions the scale of Boothby and Sandiford is used.

The author believes that high carbohydrate diets increase the difficulty of treatment and uses smaller amounts than those generally advised by Joslin. Wilder believes that with the higher carbohydrate diets a wider fluctuation of the blood sugar occurs and that it is almost impossible to keep the urine sugar free. Diets are planned with strictly limited amounts of carbohydrate and protein, it being thought that 50 grams of protein per day will cover the needs of practically every patient providing not less than 2/3 of a gram for each kilogram of body weight. An example of a 2000 calorie diet used by the author consists of carbohydrate 73, protein 50 and fat 167 grams, glucose value 120.

Whether one adopts the author's diet or follows the plan of Joslin with generally one gram of protein per kilogram of body weight and usually about 100 grams of carbohydrate per day is perhaps a matter of individual preference as good results may be obtained either way, when the patient is carefully observed.

W. E. MCCOLLOM.

PHYSIOLOGICAL CHEMISTRY. A Text-Book and Manual for Students. By Albert P. Mathews, Ph.D. Fifth Edition. Octavo of 1233 pages. New York, William Wood & Company, 1930. Cloth, $7.00.

Mathews has now gone into the fifth edition. It is readable and up-to-date, containing the most recent advances in the biochemistry of metabolism and nutrition. In addition to a very exhaustive text, it contains in the last part of the book, a 300 page manual describing all the biochemical methods employed in clinical medicine. The bibliography is quite complete. It is recommended as an authoritative text and reference source for the student of biochemistry and metabolism.

W. S. COLLENS.

RECENT ADVANCES IN BIOCHEMISTRY. By JOHN PRYDE, B.Sc., M.Sc. Third edition. Octavo of 393 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50.

The first edition of this valuable work appeared in 1926; it was stated at that time that "Biochemistry is a science of such recent development and active progress that the whole of our subject might well be embraced by the title of this little volume. My chief problem has therefore been the choice of material. It has been my aim to include as diverse as possible a selection of topics, in which the recent advances have been most striking, and in which the trend of modern biochemical research is well indicated."

In the third edition, two chapters of the previous edition have been omitted: "Colloids and the Physical Chemistry of Proteins" and "Chemotherapy." Two new chapters have been added: "Protein Structure and Proteolytic Enzymes" and "Cholane Series." A list of references to recent literature is given at the end of each chapter.

As far as the reviewer's own interests are concerned, a useful summary of the recent work of Robison and his collaborators is given under the titles "The Role of Organic Phosphates in Ossification" and "The Problem of Rickets in Relation to the Bone Enzyme." The review of "The Chemistry of Ossification" is very brief; no mention is made of many recent contributions of note.

The number of original papers in biochemistry published each year is enormous. and the number increases year by year. The only practical way for the medical man interested in biochemistry to keep abreast of the times is by the reading of reviews such as this. This applies equally to the biochemist as far as the subject as a whole, apart from his particular specialty, is concerned.

M. J. SHEAR.

A TEXT-BOOK OF MEDICINE. By American Authors. Edited by RUSSELL L. CECIL, A.B., M.D., Sc.D. Second Edition Revised. Octavo of 1592 pages, illustrated. Philadelphia & London, W. B. Saunders Company, 1930. Cloth, $9.00.

This edition appears four years after the first and is the work of 135 authors. Many changes have been made and among the new chapters are those on tularemia, snake venom poisoning, atelectasis of the lungs, brucella abortus infections and agranulocytic angina.

In covering so large a field there are many advantages in the co-operation of numerous writers. The editor states that "it is doubtful whether any author of the future will have the temerity to write a complete textbook of medicine without considerable collaboration." It is true that a book of this kind lacks something of the charm of Osler's Practice but the editor's statement can not be refuted.

The plan followed of having references at the end of each principal chapter and the full index are valuable features of the book which is unquestionably one of the best in the field of internal medicine.

W. E. MCCOLLOM.

PRACTICAL TREATISE ON DISEASES OF THE DIGESTIVE SYSTEM. By L. WINFIELD KOHN, M.D. 2 volumes. Octavo of 1125 pages, illustrated. Philadelphia, F. A, Davis Company, 1930. Cloth, $12.00.

This two-volume treatise on digestive disorders should serve as a supplementary reference book. While it does not depart essentially from other reference books on the subject there are a few points which may win the appeal of the physician.

First, the salient facts are always italicized, and second, there are many well-chosen diagrammatic illustrations to support the detailed text. If one be interested in such an unusual disorder as Tuberculosis of the Stomach he will find it well discussed in this work.

Gastric photography is clearly described and will no doubt instill hope in the reader that some day natural color photography of the stomach lining may be a practical realization.

Treatment is discussed in a conservative fashion. Operation is advised only when medicine does not help. Even in such surgical conditions as fistula or acute appendicitis expectant medical treatment is advanced with the hope of offsetting surgery.

EMANUEL KRIMSKY.

A SYNOPSIS OF MEDICINE. By HENRY LETHEBY TIDY, M.A. Fifth edition, revised and enlarged. 12mo of 1032 pages. New York, William Wood & Company, 1930. Cloth, $6.00.

As in the previous editions the book supplies a quick reference volume in the field of medicine, the general arrangement following that of Osler's Practice of Medicine. While not intended as a full text-book it is more than a brief synopsis, and a satisfactory description of each disease is given.

In this edition there are many new articles and revisions bringing the text thoroughly up-to-date. The book shows much evidence of careful work and will be found very valuable for reference.

W. E. MCCOLLOM.

BURNS—TYPES, PATHOLOGY AND MANAGEMENT. By George T. Pack, B.S., M.D. and A. Hobson Davis, B.S., M.D. Octavo of 364 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1930. Cloth, $6.00.

This single volume of 364 pages and 60 illustrations is well bound and clearly written. There is no other surgical accident which requires greater judgment and more careful attention in the wards of our large hospitals than the one under consideration. The pain suffered by a patient having a severe burn is the most agonizing in character. The usual convalescence and morbidity is usually greatly prolonged, and the cicatricial contractures and deformities are of the most serious nature. Because of the conditions mentioned above, the author has made an intensive study of this accidental calamity. He very justly states that a severe burn requires not only proper and immediate aid but also requires, too, much plastic and orthopedic surgery because of the frequent early neglect. Wherever possible, the severe burn cases should be under the immediate control of a surgeon who has had special training in its care and treatment. The chapter on scalds and burns in children is especially interesting. The subject of skin grafting occupies an important place in the book. Complete outlines of treatment are given in detail both from the medical and surgical standpoint.

This book is highly recommended for the interne staff and the attending surgeon, and equally for the general practitioner who is often first called and who equally often mistreats the burn case because of his lack of intimate knowledge of the subject.

MERRILL N. FOOTE.

RESEARCH AND MEDICAL PROGRESS AND OTHER ADDRESSES. By J. SHELTON HORSLEY, M.D. 12mo of 208 pages. St. Louis, The C. V. Mosby Company, 1929. Cloth, $2.00.

The book has fifteen interesting chapters, and following the title in each chapter he has discussed the history of many operative and clinical procedures, also the benefits or complications likely to arise as a result of treatment, both medical and surgical. Most of these chapters are reproductions of addresses given before state medical societies. They are instructive and interesting.

RALPH F. HARLOE.

THE PATHOLOGY OF INTERNAL DISEASES. By WILLIAM BOYD, M.D., M.R.C.P. Octavo of 888 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $10.00.

The trend in medicine now-a-days seems to cherish chemical and physical, bacteriological and serological methods, while morbid anatomy is looked down upon as something almost obsolete and ranking in usefulness next to normal descriptive anatomy. In other words it seems that no more progress is expected from the careful study of morphological changes occurring in disease. The average medical student does not like to study pathological anatomy and the average physician, as Boyd says in his preface, "turns to the text-books of medicine if he wishes to study the pathology of the disease." Obviously this cannot be the fault of the students and physicians only and it seems that there is a need for a different type of text-book on Pathology than most of the books published heretofore in English and German.

Pathological anatomy should be discussed with an eye as to the needs of the practicing physician, who is not interested in the minuteness of the details or in accurate classification of the various conditions. He is concerned more with the relationship of pathological processes to clinical manifestations and with the development of the pathological processes from their onset to the fatal outcome.

Boyd has tried to write a text with aims in mind similar to those outlined above. His description is vivid and always interesting. His attempt to discuss the changes in function which are either consequences or concomitant features of the anatomical changes is of great value for the better understanding of the pathological processes. His book really deserves to be read by the practicing physician and not only looked up incidentally as a source of special information.

The critical reviewer, however, will successfully try to find fault, even with such an excellent piece of work as Dr. Boyd's book. Some of his ideas, such as the relationship of angina pectoris to syphilis, are at variance with the more widely accepted opinion. His statement "That a clinical picture of coronary obstruction is comparable, but different from angina pectoris," is open to challenge. It is regrettable that Dr. Boyd takes so little cognizance of foreign, and particularly of German literature, and thus foregoes the opportunity to discuss some of the most fruitful advances in pathology, such as for instance, Ranke's conception of the three stages in the development of pulmonary tuberculosis. No mention is made either of what the German authors call "Fruhinfiltrat" or of the epituberculous lesions. In discussing congenital abnormalities of the heart, Spitzer's conception should not be omitted. Other rather important questions, such as malignant nephrosclerosis, are handled in too sketchy a manner, and the same criticism applies to the chapter on arteriosclerosis.

The pathologist will not fail to discover these and similar other shortcomings. The practicing physician, however, will read this book with pleasure and will obtain both enlightenment and stimulation.

M. A. GOLDZIEHER.

EMERGENCY SURGERY. By HAMILTON BAILEY, F.R.C.S. Volume I Abdomen and Pelvis. Octavo of 380 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $8.00.

The impression gained from a careful perusal of this volume is one of unmixed disappointment. The opening chapters seem to be written for the tyro in surgery, giving descriptions of commonplace tools and elementary principles of surgery, whereas the clinical chapters encompass some of the most complicated surgical procedures which, of course, never can or should be attempted by the occasional operator. Some of the measures advocated by the author will sound heretical to most American surgeons, for instance the advice to use gauze moistened in turpentine for hemostatic purposes or employing mercurochrome intravenously as a routine procedure in cases of appendicitis with generalized peritonitis. The apparent disregard for spinal anesthesia is very disappointing in view of its enormous advantages in most types of emergency as well as elective surgery. Again why the avoidance of such an acknowledgedly noxious anesthetic as chloroform should be emphasized nowadays is likewise a puzzle.

In view of the excellent volumes on surgery, both general and regional, which have lately appeared in this country as well as in Europe, we regret we cannot recommend this work.

GEO. WEBB.

THE BEHAVIOR OF THE NEWBORN INFANT. By KARL CHAPMAN PRATT, Ph.D. and others. Octavo of 237 pages. Columbus, The Ohio State University Press, 1930. Paper, $3.00. (Ohio State University Studies, Contributions in Psychology, No. 10.)

The Ohio University psychologists have made a very detailed study of the reactions of newborn infants to certain stimuli. The investigations involve a detailed description of the reactions which infants show during the neonatal period to light, sound, taste, smell, temperature, restraint and plantar stimulation. Observations of the sucking reflex have also been included.

The methods employed and the results obtained have been clearly shown by adequate diagrams and tables. The work is purely investigative and should be consulted by those interested in infant behavior. A quite complete bibliography has been included.

LEWIS A. KOCH.

CANCER OF THE LUNG and other Intrathoracic Tumors. By MAURICE DAVIDSON, M.A., M.D. Octavo of 173 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $5.50.

This is a carefully written, well presented work on the subject, which shows the study and experience of the author. We find the pathological and clinical conditions clearly treated and the histories of twenty-two patients discussed. From these the author has drawn his conclusions. Excellent roentgenograms are shown of many of the cases and a discussion of the pictures is given. While the reports of the cases are excellent for physical and gross postmortem findings, there is evidently no examination of these specimens with the microscope as no histological findings are given in the reports. The use of the Roentgen ray as an aid in diagnosis cannot be so general in England as in the United States, for the author writes "It is regrettable that in this country there is not more of that co-operation between the clinician and the radiologist which appears to be an outstanding feature in the leading clinics in the Unitel States."

The author states also in regard to bronchoscopy "The use of the bronchoscope as an aid to the diagnosis of various intrathoracic diseases, though it has been employed with regularity and considerable success in most of the best known American clinics, has unfortunately been a good deal neglected in this country (England)."

HENRY M. MOSES.

OUR NEIGHBORS

EDUCATION BY THE STATE SOCIETY OF VIRGINIA

The April number of the *Virginia Medical Monthly* has a "President's Message," by Dr. J. Allison Hodges, in which he discusses the various phases of medical education conducted by Virginia, as follows:

"Formerly, our State Society has exercised only two functions, scientific and business. Latterly, to these has been added another, which is educational in character, and is administered through The Department of Clinical Education, the Society's principal educational agency.

"More recently, following the original plan outlined for this Department at its initiation in 1928, two other subsidiary educational methods, which will be put into operation gradually, have been arranged for enlarging and enforcing this educational work.

"The circle of education, as arranged by the Society, and as now completed, embraces, then, the continuing education of the practitioners in their own communities under the direction of The Department of Clinical Education; the education of special groups under the guidance of the Joint Committee on Prenatal and Postnatal Instruction; and the education of the public through The Joint Committee on Public Health Education, thus contemporaneously teaching medicine to its members and health to the people.

"In presenting the resolutions to the Council for the appointment and future work of this latter committee, the President of the Society spoke in part as follows:

"'Finally, our State Society, if it would attain the summit of its usefulness, must logically benefit not only its own members, but also correctly educate the people at large. Hitherto, we have not influenced public opinion by participation in cooperative contact with lay organizations, and now, our profession, through organized medicine, must seek leadership, and by correctly educating the public in personal and public health measures, earn its cooperation.

"'Education of the people, plus continued education of the doctors, equals State Health, the surest guarantee for the future against socialized medicine, Federal methods, or rank charlatanism. We, as a profession, must face this issue in time; either we can help, or we can unworthily dodge the responsibility.

"'It is easy enough to broadcast health knowledge, but it is difficult to arouse an interest that will apply this knowledge to personal use.

"'With this new concept of an old subject, it should be an inspiring task for us to direct and enforce this knowledge, for doctors can no longer afford to stand idle on the sidelines of progressive science.

"'As a profession, we need a shift in medical thinking in order to meet properly many of the problems in this changing and challenging era. We must no longer simply coddle our fears, but be ready to present factual conclusions. We must be prepared.'"

PUBLIC RELATIONS IN VIRGINIA

The civic relations of the medical profession to other civic groups has received more attention in New York State than in probably any other State, as will be seen by the records of the committee on Public Relations published in the Journal. Now Virginia, too, is taking up the project, as is shown in the following editorial in the Virginia Medical Monthly for April:

"It is becoming increasingly apparent that the government, both Federal and State, is gradually assuming certain prerogatives, responsibilities, and functions, which have been vested in the medical profession for many years. The federalization of medicine has already, either partially or completely, become effective in twenty-eight countries of the world.

"Dr. Southgate Leigh, in his report of the proceedings of the A. M. A. at the Norfolk meeting of the Medical Society of Virginia, October 21-23, 1930, urged the immediate appointment of a Public Relations Committee to investigate this problem and make recommendations, this action being advocated by the A. M. A., at the Detroit meeting. The House of Delegates voted to adopt the recommendations of Dr. Leigh, and a committee was appointed by the President.

"The Committee met in Richmond, January 15th, for the purpose of organizing and formulating a plan of action. At the suggestion of the Chairman, Dr. W. O. Bailey, of Leesburg, Va., was made secretary of the committee.

"The committee agreed that urgent necessity does exist to take immediate cognizance of Fed-

Vitamin A	+	— to +	—	— to +	+ + +	+ +
Vitamin B (B_1)	+ + +	+ +	+	+	+	+
Vitamin C	—*	—*	—*	—*	—*	—*
Vitamin D	—**	—**	—**	—**	—**	—**
Vitamin E	+ + +	+ +	—	—	— to +	+
Vitamin G	+ + +	+	— to +	+	+ +	+

These figures are included to illustrate ordinary nutritional values. These factors no longer constitute a serious nutritional problem.

Mead's Cereal excels in minerals and vitamins. It is noteworthy that the calcium-phosphorus ratio of Mead's Cereal is 1.2.1, similar to that of average whole milk, which is considered the most favorable ratio for retention.

* ** The daily use of specific vehicles for vitamins C and D (e. g., orange juice for C and cod liver oil or viosterol for D), together with the use of Mead's Cereal, makes it possible for the physician to supply the growing child with all of the essential vitamins in substantial quantities.

Send for a package of Mead's Cereal for use in your household.

MEAD'S CEREAL contains nine minerals and four vitamins in appreciable amounts from natural sources—in addition to adequate proportions of protein, fat, carbohydrate and calories. Mead's Cereal is palatable and is advertised only to physicians. Devised in the Research Laboratories of the Hospital for Sick Children and the Department of Pediatrics, University of Toronto. Mead's Cereal is supplied in 16-ounce cartons, for sale at drug stores. Samples are available to physicians.

eral and State encroachments, and to combat them. It undertook to establish a plan of procedure to meet this vital contingency and to consider (a) How, (b) Where, and (c) By whom this action should be taken; and, further, to whom facts which have been and will be adduced should be communicated.

"In view of the above, the Committee urges the Presidents of all County Societies, and other Medical Societies in the State, to confer with the Councilors in their districts, for the purpose of assembling all the practitioners in their districts at some convenient place, at which time some member of the Public Relations Committee will meet with them and present this important matter. Any further information desired will be given with pleasure by G. F. Simpson, M.D., Chairman, Purcellville, Va."

RELIEF OF DROUGHT VICTIMS IN VIRGINIA

The *Virginia Medical Monthly* for April contains the following editorial information regarding the relief of victims of the dry weather of last Summer:

"'2,500,000 DROUGHT VICTIMS WELL-FED BY RED CROSS.'

"Nearly 2,500,000 persons in twenty-two states came under the care of the American Red Cross as a result of drought. Relief operations were the most extensive in fifty years of aiding victims in more than 1,000 disasters. Only 340 professional workers were employed on the huge task, the rest being volunteers. Local Chapters taxed their resources to the utmost before asking for funds from the National Headquarters.

"As early as last September, the Red Cross began distributing to more than 58,000 families, seed for pastures and to more than 27,000 families seed for kitchen gardens, in anticipation of the emergency. The expenditure for this purpose amounted to $326,800. Green vegetables were thus made available up to the first of January, and stock was kept alive for several months. A second garden program got under way in February, and 537,000 packages of seed were distributed. Feeding provided balanced and adequate rations. Red Cross nutritionists, together with Department of Agriculture experts, made it effective in preventing malnutrition and setting up a resistance to disease. Hot lunches were served in many schools. County health officers and private physicians commended the adequacy of rations procured on orders issued by Red Cross Chapters, which were filled at local stores. More than 500 carloads of foodstuffs were contributed. These were hauled free by the railroads, as their contribution to the cause.

"States involved were: Alabama, Arkansas, Georgia, Illinois, Indiana, Kansas, Kentucky, Louisiana, Maryland, Mississippi, Missouri, Montana, North Carolina, New Mexico, North Dakota, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Virginia, and West Virginia."

MEDICAL PRACTICE BILL IN MICHIGAN

The April number of the Journal of the Michigan State Medical Society has the following description of a bill to amend the present Medical Practice Act in ten particulars:

"The question is frequently asked: 'Why amend the present law?' The endeavor will be made to impart the outstanding reasons in tabulated form:

"1. The present law was formulated in 1899. It provides for a Board composed of regulars, homeopaths, eclectics and physio-medics. There no longer exist any of the schools of the last three specified classes. The Governors have been compelled to appoint to the Board so-called regulars. The Board is therefore illegally constituted.

"2. The present law specifies the subjects in which a candidate shall be examined for license. Some of these subjects are no longer taught in our colleges. The amendment authorizes the Board to designate from time to time the subjects of examination.

"3. The present law requires a four-year course in a medical college. A goodly number of our Class A schools permit students to complete their college work in sixteen quarters over a period of three years in place of sixteen quarters over a period of four years. The Board is not empowered to license fully trained students who have completed their courses in three years. Consequently an amendment is worded permitting the Board to license these students.

"4. Under the present law a violation is a misdemeanor. The violator cannot be arrested or tried until evidence of fact is presented. Then when arrested he can appear, give bail and resume his practice, delaying his trial for from one to two years. An amendment is prepared to make violation a felony. This will enable the Board to obtain the arrest of a violator upon information, secure an injunction to prevent practice till tried and so expedite his trial.

"5. In the wording of the present act it has been a debatable question as to whether a license can be revoked without first convicting the violator in a court of record. A recent Supreme Court decision has sustained the Board in this power but in order to block future appeals upon this

Smyrna, Sanford and Daytona Beach which was excellent but not well attended.

"Brevard County, by reason of the population of the small towns and the distance to be traversed by the various doctors to the meeting place, is to be congratulated upon its attendance. The Society itself is in harmony and is doing good work. Some of the individual members have been annoyed by the actions and the practices of a non-member physician, who, they report, is guilty of renegade practices and twenty five-cent medicine. A. M. A. pamphlets on medical ethics were procured and forwarded to the Society."

The Tenth District Councilor had an easy assignment, according to his report.

"I attended a meeting of the Polk County Medical Society recently, which as you know comprises the tenth district, of which I am Councilor.

"The Secretary of this Society advises me that as far as he knows there is not a single practitioner eligible for membership in the Polk County Medical Society who is not a member, although there are several who have not paid their 19 dues and are, therefore, not in good standing.

The Councilor of the Twelfth District has few doctors in his field, and they are scattered. However, he makes an excellent report, as follows.

"As Councilor of the twelfth district, which comprises the counties of Glades, Charlotte, Hendry, Lee, and Collier, I have been in communication by letter with every doctor in the district who is eligible for membership. With the exception of Lee County, there are not enough physicians in the four other counties to form a medical society. For this reason, it is very difficult to stimulate interest in attendance at district meetings. Then, too, for the most part, the physicians are located quite a distance from a city and some of them would have to make a trip over bad roads. However, Dr. Stebbins of Charlotte County, holds membership in the Lee County Medical Society.

"The Lee County Medical Society holds regular meetings the third Friday evening of each month at the Lee Memorial Hospital. For the sake of variety, and to stimulate interest, sometimes the meeting takes the form of a dinner. We have an average attendance of 90 per cent, all but two of the eligible physicians of the County being members. We have gained one new member this year, which brings our membership up to eleven members. Twelve regular meetings were held the past year and one called meeting. We endeavor to have interesting, constructive meetings, with a scientific paper by a member, followed by discussion of the subject. I think that our percentage of attendance proves that the meetings are well worth the time devoted to them."

These examples taken in the order of the publication, show a cross section of County Societies in the State of Florida. The rural doctors of Florida are to be congratulated on their interest in the practice of civic medicine, and in the friendliness to one another. Much of the credit for the progressiveness of the Societies belongs to the Councilors, who are liaison officers of the State Society.

DROUGHT RELIEF IN ARKANSAS

The Council of the Arkansas Medical Society met on February 13 and considered the serious problem confronting rural physicians in their efforts to administer to the indigent sick of the drought-stricken sections of the State. The Journal of the Arkansas Medical Society reports the meeting as follows:

"Dr. C. W. Garrison, State Health Officer, addressed the meeting, the substance of his remarks being as follows: Congress has appropriated $2,000,000.00 to be administered by the U. S. Public Health Service through the State Departments of Health in the 22 drought-stricken States; the funds are made available for investigation and health demonstration work, for medical supplies and biologicals; the allocation to each State and community to be based on the local ability to pay and the needs, at the discretion of the Surgeon-General.

"Each State Health Officer has been requested to draft an outline or proposal for his State and submit it promptly to the Surgeon-General for consideration and approval."

Following a general discussion, the Council adopted the following Resolution:

"*Resolved*, that the need for financial aid in almost every county is very urgent, and will continue unabated for a considerable time.

"That sickness will be more prevalent than usual, due to lack of physical resistance because of the under-nourished condition of many of our people.

"That provision has been made to some extent for their physical condition, but none for medicines or hospitalization.

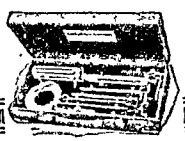
"That Arkansas' proportion of the $2,000,000.00 appropriated by the Federal Government should be made available immediately and with the least restrictions possible under the law and that a reasonable proportion be allocated for drugs and biologicals; and that these supplies be also made available for use in hospitalized indigent cases.

"That immediate action is most necessary as doctors who have always given freely of their services are now in some cases unable longer to do so, and their transportation, medical and surgical supplies should be furnished them when attending our indigent sick.

"That if such relief for the physicians under the Federal appropriation above referred to is unavailable or inadequate that it is the sense and desire of this council that every effort be made to secure this aid both for the relief of the physician and service to the people."

ELECTRICALLY LIGHTED SURGICAL INSTRUMENTS

FOR YOUR PROTECTION
Look for the Mark
"E. S. I. Co."



On electrically-lighted diagnostic and surgical instruments.

For protection, every instrument bears the imprint "E. S. I. Co." All are original achievements developed under the careful guidance of American medical authorities, and are sent to you only after being inspected critically and tested thoroughly.

There is an "E. S. I. Co." electrically-lighted instrument for specialists in practically every field.

REST IN GASTRO-INTESTINAL DISEASE

In the collected papers of the Mayo Clinic, 1927, Alvarez writes of his experience in the diagnosis and treatment of gastro-intestinal disease. Rest, refreshing sleep and relaxation of the patient he found to be most important in many cases and the most useful drugs to be not pepsin or bismuth, but sleep-producing medicaments. To a description and notes on dosage of several hypnotics, the author adds: "All these drugs are best given early, when the patient goes to bed. An exception can be made in the case of Bromural which even if taken late, in doses of from 5 to 10 grains, works quickly and has no tendency to bother the patient next morning. It is one of the best drugs I know for calming nervousness during the day."

Literature and samples of Bromural may be obtained from Bilhuber-Knoll Corp., 154 Ogden Ave., Jersey City, N. J. See page xxvi.—*Adv.*

LILLY RESEARCH LABORATORIES

Few drugs have attained greater prominence in a shorter period of time than Sodium Amytal, the sodium salt of iso-amyl ethyl barbituric acid, a product of the Lilly Research Laboratories. In a measure its quick adoption can be traced to the wide use of Tablets of Amytal, a Lilly hypnotic that has long rendered excellent service and proved particularly pleasing to physicians, because it leaves no undesirable after-results and produces sound, refreshing sleep.

The sodium salt of Amytal has a wide range of uses. In surgical patients it reduces pre-operative anxiety. It lessens the quantity of inhalation anesthetic required, diminishes nausea and other objectionable postoperative features. The obstetrician notes relaxation of the perineal muscles and unusually rapid softening of the cervix following the oral administration of Sodium Amytal.

The physician in general practice finds Sodium Amytal effective either by mouth or by rectum for the production of mental and physical rest in acute and chronic ailments, for the control of convulsions, and, in conjunction with analgesics, for pain relief.

Pulvules Sodium Amytal, No. 22 are supplied through the drug trad Literature is available on application Eli Lilly and Company, Indianapoli Indiana. Color Insert—*Adv.*

MANAGEMENT OF DIABETES*

By STEPHEN H. CURTIS, M.D., TROY, N. Y.

DURING the past six or eight years, there has been an unprecedented interest in the study and treatment of diabetes mellitus. No doubt, the remarkable discovery of insulin by research workers at the University of Toronto in 1921 and its proven value as a specific has added materially as a stimulus to our interest.

The prevalence of diabetes is forcibly called to our attention by the number of diabetic patients who present themselves for treatment, hoping that a cure has been discovered. Approximately one person in each one hundred of our population is shown by statistics to be a sufferer from this disease. At first, hospital care of these patients is desirable as education in the management of themselves is essential and this can best be accomplished under competent supervision. It is difficult, however, for many of these patients to go to the hospital and a means must be found to give them adequate care at home. I feel that a two-week sojourn at the hospital at the beginning of treatment is invaluable subsequently, to both patient and physician. The patient can be taught the significance of blood and urine analysis, body weight, metabolism regulation of diet and insulin, if required. A thorough understanding of these essentials by the patient assures cooperation and subsequently better results.

Diagnosis: A correct diagnosis is essential before beginning any treatment. The old cardinal symptoms of diabetes mellitus, namely, polyphagia, polyuria with glycosuria, polydypsia and malaise, usually manifest themselves clinically in well marked cases. Transient glycosuria following the ingestion of a heavy meal, renal diabetes and diabetes insipidus must be differentiated. In any case the history is of importance and urinalysis will usually clear the diagnosis.

Diabetes of renal origin may be detected by a simple test. A definite amount of carbohydrate by weight is added to the diet for a day. The increased output in the twenty-four-hour specimen of urine is relatively small. In diabetes mellitus all or nearly all of the added carbohydrate is recovered in the twenty-four-hour specimen. Diabetes insipidus produces a tremendous output of urine with a specific gravity of 1.000 to 1.010 and without trace of glucose; while in diabetes mellitus the specific gravity is 1.020 or over, usually with the presence of glucose. In diabetes insipidus and renal diabetes, the blood sugar level is 90 to 120 mgs. per 100 c.c. of blood, while in true diabetes the blood sugar level is above 120, two hours after eating a meal containing an ordinary amount of carbohydrate. In untreated cases appearing for the first time for examination it is very common to find the blood sugar level between 200 and 300 or over.

An important point to stress here is that sugar is not always present in the urine in cases of true diabetes examined casually . We often find patients carrying a blood sugar level as high as 180 and occasionally up to 200 without trace in the urine at the time of examination. If the history of the case and clinical findings suggest diabetes mellitus, the blood sugar estimation should be made. Primary true diabetes may be suspected and often found in cases of obesity, dimness of vision due to cataract formation, persistent neuritis, endarteritis of the extremities with or without gangrene, pruitis, ulcers and recurring skin infection.

Pathology: In diabetes, the primary pathology is in the islands of Langerhans in the pancreas which, having become impaired has resulted in a deficiency in the required amount of insulin secretion. This impairment of function may be due to a sclerosis of the islands because of an insufficient blood supply; functional disturbances through the autonomic nervous system; and outside pancreatic disturbances, tumors, infections, etc.

The sclerotic type is usually subsequent to a general arteriosclerosis and the prognosis as regards permanent remission of symptoms is not good. In the functional disturbances, over-eating is a common provocative, disturbances in other endrocine glands may influence the functioning of

* Read before the Rensselaer County Medical Society, April 15, 1930

the islands; acute inflammation of the whole pancreas may occur following a general infection. This is particularly true of la grippe. The prognosis is good under proper supervision in these cases. In primary or secondary tumors of the gland the prognosis is not good. Congenital defects in the Islands as seen in children vary greatly in severity. Many make good recoveries, others under compensatory treatment progress well and some show no improvement.

Metabolism: Food furnishes heat and energy to the body. The three principle elements of food are protein, carbohydrate and fat. Protein provides the amino acid which promotes growth and which replaces wastes of muscle and organ tissue. The average requirement for an adult at rest is about ⅔ gram per kilo of body weight, increasing to 1 gram per kilo during physical work or exercise. The total number of calories required in 24 hours at rest is approximately 22 C. per kilo of body weight. So the difference between the total required and the protein required must be made up of the carbohydrate and fat.

In diabetes there is an inability on the part of the body to store and oxidize glucose adequately, and it therefore becomes necessary in this disease to supply only that amount of glucose which can be properly utilized. It is important to remember that 58 per cent of the protein, and 10 per cent of the fat intake, as well as 100 per cent of the carbohydrate may be converted in the body into glucose. With this fact in mind, it is really easy to realize the added harm in attempting to feed a diabetic patient on high protein foods such as eggs, meat and fish. If the protein in the diet is kept low, the patient will be able to consume more carbohydrates without hyperglycæmia and more fat without acidosis.

In the normal person, the glucose in an average meal, varying from 50 to 150 grams, is transformed into glycogen and stored in the liver and other body tissues where it is available to be reconverted into glucose when needed to supply heat and energy production. The ability to store sugar as well as to burn it is impaired in diabetes and consequently the excess remains in the blood stream. Nature tries to compensate for this by getting rid of as much as possible of the excess through the kidneys. The kidney tolerance point or that amount of sugar in the blood stream to produce glycosuria varies considerably. In many cases, I have seen it as high as 200 mgs. per 100 cc. while in a few cases as low as 120 mgs. The average blood sugar level necessary to produce glycosuria is somewhere between these two points. Primary cardio-renal-vascular diseases undoubtedly have an influence on this factor.

Treatment: As I stated briefly before, education is of paramount importance in the successful management of diabetes. The physician should explain to the patient the nature of the disease, the necessity of proper balanced diet and personal hygiene in such a way that he will thoroughly understand it. Also the patient should be familiarized with insulin, as to its therapeutic value and administration whether it is used at the time or not. This will sometimes save embarrassment if later it should be required, the patient will understand the reason and not be discouraged. Some patients take much more kindly and intelligently to the routine than others. The results show which have cooperated. Most of my patients learn to test their own urine for glucose and some also learn to test for acetone and diacetic acid and are able to get accurate interpretations. I supply a scale, and food value charts. The diabetics are soon able to choose their own menus and either the patient or a member of the household acquires the technique of setting them up by exact weight.

Total amount of food or caloric requirement: There are many factors influencing the caloric requirement. These are mainly age, sex, weight, height and occupation with the basal metabolic rate requiring consideration particularly if it is above +20 or below —20. The basal caloric table which Sandiford of the Mayo clinic worked out is very useful. Roughly however, I take 10 calories as the basal caloric requirement per pound of body weight for persons with an average normal basal metabolic rate, between the ages of 20 and 60 years. The patient may be overweight or underweight at the time he presents himself for examination. I try to estimate at that time what his average weight ought to be, allow 10 calories per pound at that figure and take that figure as the basal caloric requirement. I build up his diet to hold this weight. If the patient is confined to bed, I begin with the basal caloric amount. If exercise is very moderate, I add 10 to 15 per cent, if moderate, 20 to 30 per cent and active exercise 40 to 50 per cent. Many times at the beginning of treatment the blood sugar level is high and acidosis is present and this rule has to be discarded temporarily. It may be necessary to go below the basal caloric requirement, with or without the use of insulin to bring these down to normal. This should be accomplished first, the patient being kept in bed. Finally the diet given should be just sufficient to keep the weight at the determined average normal, the blood sugar at 90 to 120 mgs. and no acidosis, It is better to keep diabetics just a little under the normal average weight of a normal person.

Requirements of the food elements. C. P. F.: In as much as the body forms glucose from both protein and fat, as well as from carbohydrate and forms ketone bodies from both protein and fat, it is necessary to calculate the total available glucose anti-ketogenic, and the total fatty acids,

which are ketone producers, in order to provide a well-balanced diet. It is considered best to use a diet containing one and one-half as much fatty acids as glucose because this can be done without using a large amount of glucose yet with enough fat to give it high caloric value without at the same time being likely to produce acidosis.

The ketogenic-antiketogenic ratio is the amount of ketone producers in the diet in relation to the total glucose which can be obtained in the process of digestion of the food in the diet. It is as follows: 46 per cent of the protein and 90 per cent of the fat form fatty acids which subsequently break down to form acetone and ketone bodies, and thus fatty acids equal 46 P+90F. Glucose is the antiketogenic factor in the diet, and is derived from carbohydrate, protein and fat. Remember that all of the carbohydrate, plus 58 per cent of the protein, and 10 per cent of the fat, is converted into glucose in the body.

First determine the basal caloric requirement. It is estimated that normally about one seventeenth of the total calories should be from glucose, and that about two-thirds of a gram of protein should be allowed for each 2.2 lbs. of weight. The amount of carbohydrate therefore, would be equal to .8 of the total glucose required, minus one-half of the protein; and the amount of fat would be equal to twice the amount of carbohydrate, plus one-half the protein.

$$G=1/17 \text{ total calories}$$
$$P=\tfrac{2}{3} \text{ body weight in kilos.}$$
$$C.=\frac{8G}{10}-\frac{P}{2}$$
$$F=2C+\tfrac{1}{2}P$$

An example case: Man, 50 years of age. Height, 5 ft. 8 in. Weight, 160 lbs. Has a basic caloric requirement of 1,600 calories. Add 30% or 480 calories. 1,600+480=2,080 calories or actual requirement. For convenience we abbreviate P. for protein, F. for fat, C.H. for carbohydrate. Following the formula therefore:

P.=53.3 grms.

The glucose requirement = 1/17 x 2,080, or 122.5 grms.

Therefore, C. H.=(8/10 x 122.5)—(½ x 53.3)=71.4 gms.
F=(2 x 71.4)+(½ x 53.3)=169.4 gms.
Therefore the diet for this case would be

P=53 grms.
C.H.=71 grms.
F.=169 grms.

In children we use 1.5 grms. of protein per kilo so as to keep the fat intake low, and prevent acidosis to which children are very susceptible.

When and How to Use Insulin: There are several conditions under which insulin should be used, first, if after having the patient on the proper diet for a week, there is a failure to bring the blood-sugar level down to normal; second, when the patient at first examination shows acetone and diacetic acid, either or both, in the urine; third, in the presence of a complication or co-existing disease.

It has been estimated that one unit of insulin will metabolize 2 gms. of carbohydrate. In the first type of condition, we determine from the blood sugar test during the week, just how much natural carbohydrate metabolism the patient has, subtract this from the amount which the patient ought to have normally to take care of the proper diet, and give one unit of insulin for each 2 gms. of carbohydrate in the difference. This amount of insulin will usually be between 5 and 30 units, and may be divided into 1, 2, or 3 doses per day, the maximum dose not over 20 units, and best given before breakfast. This will take care of the excess blood sugar, the diet remaining constant, and should be continued until the blood sugar level becomes normal. Whether or not the

insulin should be continued indefinitely depends entirely upon the recuperative powers of the islands of Langerhans. The total amount of insulin administered per day must be in proportion to the blood sugar excess, and so this will necessitate a change in the insulin dose every few days. We always are hopeful that it will steadily decrease to the point where none is required. Daily examinations of the urine are very helpful in estimating the drop in the blood-sugar level, and must be relied upon in cases treated at home, or where they can not be seen each day and blood examinations made.

After the insulin has been stopped and the patient is holding the estimated normal average weight, it is necessary to check up at weekly intervals on the blood-sugar level, urine for acetone and diacetic acid, and the body weight. If everything goes well, make no changes. If the weight has dropped a trifle increase the diet at the rate of 5 gms. of carbohydrate and 10 gms. of fat, keeping the protein at a trifle less than 1 gm. for each 2 pounds of body weight. If the weight is increasing, drop the diet at about the same ratio. There are cases in which it is necessary to resume the administration of insulin for varying intervals in order to hold everything in balance. This is easy to do, as by this time the patient has had a fair education on this subject and realizes that it provides him normal comfort and he is quite willing to cooperate.

In the second type of cases, we are unable to balance the diet on the start, as it is necessary first to combat the acidosis. The carbohydrate must be increased and the fats and proteins decreased, because of the over-production of fatty acids. This condition is often seen in patients who present themselves after having been on rigid low carbohydrate or starvation diets for some time. Insulin is administered in the ratio of one unit for each 2 gms. of carbohydrate contained in the diet. This is continued for a few days only until the acidosis clears up and then the patient is put on the properly balanced diet with or without insulin as findings require.

In the third class of cases there is no rule to follow. It is a question of judgment in adjusting conditions as they are found to get the patient into the first class as rapidly as possible. No progress can be made until this can be done. Severe cases of acidosis result in coma, and here the treatment consists of maintaining an alkaline reserve in the blood stream, active elimination, and clearing up the toxemia by administering glucose and insulin to burn up the excessive fatty acids.

In the administration of insulin, the condition of hypoglicæmia must be watched. The symptoms which arise shortly after the administration of insulin, manifest themselves first as a sudden hunger, followed by restlessness and weakness; the face becomes pale and then flushed; and the pulse rate is increased. If the overdose is sufficiently large, these symptoms are exaggerated, and there is sweating, muscular tremor, anxiety, and fear. Recovery is quite rapid after the administration of carbohydrate in liberal quantities. Orange juice, sugar, or candy will suffice. In rare instances however, this condition may go on into convulsions, coma, and death. I have not seen this happen yet, and hope I never will. It is well to remember that the use of insulin over long periods continuously, may stimulate the thyroid gland to over-secretion; and we then see symptoms of hyperthyroidism.

Conclusion

After the diagnosis of true diabetes has been established, the management depends, first, upon appropriate regulation of diet and exercise, and second, upon insulin to make up the deficit where it exists. There is no stated dose of insulin. It must be determined for each individual case. In most cases 30 units a day is the maximum required. Occasionally larger doses up to 60 or 80 units a day may be required, as in coma or in severe infection, and this only for a very short time. The patients are taught the fundamental principles of the treatment and soon learn the technique. If insulin is to be required indefinitely, the patient is taught to administer it to himself.

Some points to keep in mind:

1. Diet is more necessary than insulin without it.
2. Body weight should be kept slightly below normal average.
3. If a meal is omitted, so should the preceding dose of insulin be omitted.
4. Insulin should not be discontinued suddenly without checking up on the blood-sugar level.
5. Insulin is best given thirty minutes before the meal.
6. Hypoglycæmia is more serious than hyperglycæmia.
7. Acidosis is more serious than hyperglycæmia. Watch for acetone and diacetic acid in the urine.
8. Acute uræmia may cause coma instead of acidosis.
9. Insulin should be injected deeply into the subcutaneous tissues and not repeatedly in the same area.
10. Always sterilize the syringe with steam or boiling water. Alcohol renders insulin impotent.
11. Insulin by mouth has no effect at all.
12. The caloric index of the patient is his weight, and not his mind or appetite.

FACTORS IN THE INCINERATION OF COMMUNITY REFUSE

By ROBERT J. BARTLEY, C.E., BAY SHORE, N. Y.

IN the Metropolitan District of New York and New Jersey there are several hundred refuse incinerators, municipal, industrial, institutional, apartment house and domestic, in daily operation, without sensible nuisance. Therefore, it is hardly necessary in this enlightened age to advance arguments for the incineration of refuse as against its disposal by other methods. The other methods, particularly of garbage disposal, such as dumping on land or at sea, rendering in chemical plants or feeding to hogs on local farms, are either unsanitary, unsightly or unbefitting to a community of culture and substance.

It is simply a question of time, policy and availability of funds when every community will be served by an incinerator for the destruction of its refuse. Once the policy is decided, it is necessary to determine the requirements of a community in terms of incinerator capacity best suited to the economical, orderly and efficient disposal of refuse. There are statistics and precedents for estimating the required incinerator capacity of a community from the average per capita production of refuse according to the various classes of population. It is better, however, to make a fact-finding survey in each case, and to determine the quantity and character of refuse to be burned, the maximum seasonal population in the year of the survey, and the anticipated population twenty years hence. The life of a well built incinerator plant should be twenty years or longer and it would be poor economy to have it become obsolete at an appreciably shorter period, due to being under-sized. The fact-finding survey should cover every source of refuse from clubs, hotels, restaurants, markets, stores and hospitals as well as from private homes. It is a comparatively easy matter to increase or decrease the facilities for the collection of refuse by putting on more wagons or trucks, or by laying them off, as the needs may be; but the capacities of built-in furnaces cannot be changed overnight, and alterations, extensions and additions are usually more costly per unit of capacity than the original installation. It is necessary to figure on peak loads with reasonable excess capacity for growth in population.

Plant Location.—Having arrived at the proper figure of capacity from a study of actual quantities of materials and population, the land requirements for plant and approaches are readily ascertainable from prevailing practice. The next step is the selection of a site for the plant. From the point of view of absence of nuisance in the proper combustion of refuse, it is conceivable that a plant could be located in the heart of residential community or in its business section. This is, in fact, being done every day with the built-in incinerators in hotels, hospitals, apartment houses and office buildings. In these cases, however, the refuse is produced within the building where it is burned. In the case of a community incinerator, the refuse must be collected from house to house and transported to the incinerator. It is the system of collection that is more likely to be the subject of complaint than the actual destruction of the refuse. The location of the incinerator is of primary importance for the economical delivery of the material to be burned. It should be central to the area served, and, at the same time, sufficiently isolated so as not to make the residents unwilling reviewers of the daily parade of teams and trucks converging at the delivery point.

Principles Governing the Combustion of Refuse.—The burning of garbage with rubbish resolves itself into the de-watering and burning of the trimmings, parings, plate waste and spoilage of human foodstuffs, with the addition of a waste fuel. The waste fuel is rubbish which consists chiefly of cellulose in the form of newspapers, wrapping paper, card-board boxes and containers manufactured from wood after extraction of the resins and lignin. The fuel value of rubbish is essentially that of wood or wood products. The richer the rubbish is in these products, and the less incombustible it contains, such as bottles and metal scrap, the more closely will its fuel value approach that of wood or cellulose. Mattresses and bed springs sometimes find their way into the rubbish collection; the former increase the fuel value while the latter decrease it by the cooling effect and by replacing combustible. Garbage itself is as rich in heat units per pound of dry material as is rubbish, but garbage will not support combustion until its high content of water has been reduced by evaporation. The heat units in garbage are derived from the cellulose and pectins in vegetable matter, and to a lesser extent from animal and vegetable fats.

The practical unit of heat is the mean or average British thermal unit, which is the 1/180th part of the heat required to raise the temperature of 1 pound of water from 32° to 212° Fahrenheit.

Composition of Garbage. The average proximate analysis of New York City garbage is given by Parsons, Hering and Whinery as follows:

Moisture	68.5%
Volatile Combustible Matter	22.7%
Fixed Carbon	3.7%
Ash	5.1%

Which Includes Fat.....	5.1%
B.t.u. per lb., dry basis	8,936
B.t.u. per lb., as received	1,926

These figures represent the properties of a large run of material from a large community nearby to our own. Furthermore, they agree quite well with the results of a systematic examination of the garbage of Washington, D. C., made throughout a 12 months period by Mr. I. S. Osborn with the co-operation of the U. S. Bureau of Soils (House Document No. 661, 1916). The average results on samples from 51,718 tons of garbage collected from January to December were:

Moisture	73.8%
Total Combustible	22.5%
Ash	3.6%
	99.9%
Which includes Fat (Ether Soluble)	5.1%

The average results of the proximate analyses of two large and extended series of independent examinations are sufficiently concordant to justify the use of the more complete New York City figures as a basis for the estimation of the heat required to burn garbage.

Let us see how much heat is required to bring such garbage to a combustion temperature of 1250° F., since experience has shown that at lower temperatures there is incomplete combustion and an escape of objectionable gases.

The heat required to evaporate the moisture and superheat the resulting heat to the temperature of combustion is found in B. t. u.'s per pound of material from the following formula: $Q = W[(212 - t) + 970.4 + 0.47(T - 212)]$ where W equals the percentage of moisture per lb. of garbage; t is the initial temperature of the garbage; 970.4 is the heat of vaporization of one pound of water; 0.47 is the mean specific heat of steam between 212° and 1250° F., and T = temperature of the combustion process, or 1250° F. With New York City garbage of the average proximate analysis as given above, and with the initial temperature of 32° F. and the final temperature of 1250° F., the heat required to raise the moisture in one pound of garbage to the temperature of the combustion process would be,

$$0.685\ [180 + 970.4 + (0.47 \times 1038)] = 1122 \text{ B.t.u.}$$

Heating the Air Used in Combustion.—From the law of the conservation of matter, the *weight* of the gaseous products of combustion together with that of the air in which the combustion has taken place, must equal the weight of the combustible (ash and moisture free), plus the weight of the air introduced for the combustion. Since the specific heat of the gases of combustion and excess air may be taken as the same as that of air at the same temperature, without appreciable error, the total heat required to raise the combustible plus the combustion air to 1250° F. may be found by taking the sum of the weights of combustible per lb. of garbage and combustion air per weight of combustible, and multiplying this sum by the specific heat of air .24; and then multiplying this product by the difference between the initial and final temperatures. If 18 lbs. of air are used per lb. of combustible (ash and moisture free), the quantity of heat for 1 lb. of garbage containing 26.4% combustible, would be,

$$(18 + 1) \times (0.264 \times 0.24 \times 1218) = 1466 \text{ B.t.u.}$$

18 lbs. of air per lb. of ash and moisture free combustible is about the same quantity of air that is used in burning carbon or coal. As a matter of fact, the higher volatile content of garbage combustible in volatile combustible matter (V.C.M.) justifies the use of larger quantities of air, and it will be found in incinerator practice that 18 *lbs. to* 24 *lbs.* of air are used *per lb. of ash and moisture free combustible* in the *mixed refuse.*

Heat for Inert Material.—Heat is also required to raise the inert material in the garbage to the temperature of the combustion process. With the small percentage of ash in the garbage under consideration, 5.1% of specific heat of 0.18 to 0.20, this quantity is almost negligible, amounting to 11 B.t.u. It may not be negligible when the garbage contains an excessive quantity of tin cans or glass bottles.

Summing up the heat requirements for the combustion of one pound of garbage of the proximate analysis given above, we would have, then:

	B. t. u.
0.685 lbs. water from 32° F. to steam at 1250° F.....	1,122
0.264 lbs. combustible + (18 x 0.264 =) 4.75 lbs. air from 32° F. to 1250°	1,466
0.051 lbs. ash from 32° to 1250°..	11
Total	2,599

Previous analysis, however, has shown that the same garbage contains only 1,926 B.t.u.'s per lb. as received. Therefore, the garbage is short, 2,599 — 1,926 = 673 B.t.u.'s per lb., of the heat necessary for its combustion. This deficiency must be supplied by added fuel. If coal with 14,000 B.t.u.'s per lb. were used, it would take 0.42 lbs. of coal per lb. of garbage. Practically and economically, household refuse is used as the fuel instead of coal. Household refuse may be regarded as a waste fuel of a trifle lower heating value than saw-mill waste or sugar-cane residue after the sugar has been extracted.

Fuel Value of Rubbish.—Let us now look into

the fuel value of rubbish from the same sources as the garbage in order to keep the comparison within practical limits. First of all, a word as to the adequacy of the supply of rubbish. In the Parsons, Hering and Whinery report and from subsequent data, the average proportion of rubbish to garbage in New York City over a twelve-year period was 870:1, 454, or 37.4% rubbish to 62.6% garbage.

The proximate analysis of the rubbish studied in the *Parsons, Hering and Whinery report* is given as follows:

Moisture	11.5%
Volatile Combustible Matter	40.4%
Fixed Carbon	40.5%
Ash	7.6%
	100.0%
B.t.u. per lb., dry basis	7,713

Carrying out the same series of computations for the rubbish as was done in the case of the garbage, the following heat requirements will be found for the combustion of one pound of rubbish:

	B.t.u.
0.115 lbs. water from 32° F. to steam at 1250° F.	188
0.809 lbs. combustible + (18 x 0.809=) 14.56 lbs. air, from 32° F. to 1250° F.	4,493
0.076 lbs. ash from 32° F. to 1250° F	17
Total	4,698

The heat content of the rubbish was found to be 7,713 B.t.u. per lb., dry basis The rubbish, as received, however, was diluted so to speak with 11.5% moisture and 7.6% inert material or ash. The fuel value of the rubbish as delivered would be reduced to,

7,713 — (0.191 x 7,713) = 6,240 B.t.u. per lb. as received.

There is present in the rubbish an excess of 6,240 — 4,698 = 1,542 B.t.u. per lb. over and above the requirements for the combustion of the rubbish.

Coming back to the proportions of the materials as received, 37.4% of rubbish and 62.6% of garbage, the heat balance for one pound of this mixture of garbage and rubbish would be 0.626 x 673 = 421 B.t.u.'s additional required for the combustion of the garbage, and 0.374 x 1,542 = 577 available for that purpose from the rubbish, in excess of the requirements of the rubbish for its own combustion. There is therefore a surplus of 577 — 421 = 156 B.t.u. per lb. of refuse over and above the theoretical requirements for the combustion of both garbage and rubbish in the proportions as received. This surplus would be equivalent to over one ton of coal per 100 tons of refuse.

The foregoing is merely a numerical demonstration of the principles upon which the incineration of refuse, consisting of garbage and rubbish, is based. In practice, the processes of evaporation, gasification, and combustion take place in rapid succession and are usually going on simultaneously in different parts of the same furnace. Experience all over the world has demonstrated that with the newer types of plant the incineration of garbage and rubbish is practicable without nuisance and without purchased fuel. Our calculations show how this is possible.

There are other factors, which for the sake of simplicity, we have not dwelt on. Among them is the heat lost from unburned carbon in the ash, which can be calculated from an analysis of the ash. Likewise, all of the *excess* heat units in the rubbish are not available for the burning of garbage, nor are all of the remaining heat units in the rubbish and garbage quantitatively convertible into processes of evaporation water and elevation of the temperature of the mass to the temperature of combustion. From the total heat units contained in the garbage and rubbish there are fractional losses all along the line of heat carried away in the ash and chimney gases and lost by radiation. The complete balance may be calculated from the analysis of the materials before and after combustion, from temperature measurements in combustion chamber, stack and ash-pit and from constants of the furnace. The losses from incomplete combustion of the gases, as evidenced by the presence of carbon monoxide, are negligible in good practice as shown by the following typical analysis of the stack gases of an incinerator in full operation:

Time A. M.	Carbon Dioxide Per Cent	Oxygen Per Cent	Carbon Monoxide Per Cent
9:21	1.6	18.4	0.0
9:52	3.8	16.2	0.2
10:06	2.2	18.0	0.0
10:34	5.0	15.0	0.0
11:06	2.2	14.0	0.0
11:21	5.0	14.4	0.2
11:33	6.4	13.2	0.4
11:55	10.0	9.4	0.2

The complete combustion of the organic substances in garbage to the end products of carbon dioxide and water is not accompanied by the presence of odors. Incomplete combustion from any cause is characterized by the formation of odorous and noxious intermediate products. The odor of burning fat, due to acrolein, a condensation product of glycerine, is familiar to all. In all attempts to recover useful substances from organic wastes such as garbage, industrial wastes, sewage sludge, etc., by fermentation, dehydration or extraction, the formation of intermediate

products is unavoidable, hence these operations are necessarily accompanied by odors.

The realization of complete combustion of refuse is made possible by proper furnace design, with particular reference to the maintenance of sufficiently high temperature, an adequate supply of atmospheric oxygen, and ample space in the high temperature zone for the thorough mixing and burning of the gases.

Designs of Combustion Units.—Reduced to the simplest terms a combustion unit comprises fire grates, combustion chamber, flues, and chimney, adequately supported and lined throughout with a refractory lining; together with the necessary provisions for charging, stoking and ash removal. This layout is capable of much elaboration, chiefly along the lines of mechanical devices (1) for draft, forced or induced, and (2) for the handling of materials before or after their combustion. Waste heat boilers may be interposed between the combustion chamber and the stack. Systems for preheating the combustion air are in general use.

Furnace Proper.—"The principal factors in furnace design leading to high efficiencies and high boiler capacities are, proper furnace volume, and a furnace form which will give the longest possible flame travel with low gas velocities." (Arthur D. Pratt in Mark's Mechanical Engineers' Handbook.) The same fundamental principles apply with equal force to the design of garbage furnaces as well as to boiler furnaces, the ultimate goal in both cases being complete combustion; in the case of garbage furnaces for the purpose of odorless destruction, and in the case of steam boilers for the purpose of fuel economy.

In connection with furnace volume, the grate area per pound of material at the normal charging rate is important. When the charging rate cannot be predicted with sufficient accuracy, the grate area per ton of rated capacity may be used in design. Ample space between the grates and the stack is necessary for the intimate mixture and combustion of the gases, as well as for subsidence of dust particles. Accessibility to the interior of the furnace for stoking and cleaning is also to be considered.

In connection with the furnace form, the length and course of flame travel are all important. By suitable baffling, the length of flame travel may be increased to two or three times the overall length of the high temperature zone.

The length of flame travel, the space arrangement in the combustion chamber, and the draft are the factors which control the velocity of the gases. Low gas velocities are desirable at certain points in order to permit of thorough combustion of the gases.

Chimney designs are fairly well standardized for known quantities of combustible material and combustion air, and no legitimate expense should be spared to provide safe foundation, substantial construction, and adequate draft.

In addition to the general principles for thorough combustion, there are other factors having to do with the durability of the furnace. The temperature gradients from the grates into the combustion chamber, flues and stack should be such as will not subject standard materials of furnace construction to conditions for which they were never intended. In order to conserve heat, the radiation losses should be reduced to a reasonable figure, but excessive insulation and a high temperature of preheated air may make possible temperatures much higher than necessary and thereby seriously damage the grates and furnace lining. Uncovered metal parts are subject to chemical corrosions. In view of the condition that refuse furnaces are cold for the greater part of the twenty-four hours, and are then raised to a temperature of at least 1250° F. and maintained thereat for a period of from 5 to 10 hours, and that this cycle is repeated day after day, year in and year out, it is necessary to make ample provisions for the expansion and contraction of the materials used in construction.

Disregard of the fundamental principles in the early days of garbage incineration was the cause of many failures, burn-outs and break-downs. Incinerator manufacturers have learned from experience to embody most of these principles in their design, although there are still some anachronisms, and now and then innovations crop out which are neither conducive to economy, efficiency nor durability. Therefore, it is the duty of the public officials or engineers entrusted with such projects to incorporate in the specifications and form of contract suitable guarantees binding upon the manufacturer or contractor for the complete protection of the purchaser-community.

The present tendency is to build plants with multiple combustion units. In designing plant capacities for peak loads and anticipated growth in population, the advantages of multiple units are obvious. One unit may be sufficient to take care of average winter conditions with only occasional use of a second unit, possibly on consecutive Sundays and holidays. The two or more units together should be more than sufficient to take care of the summer load with ease, a certain excess of capacity having been allowed for growth in population. Multiple units of suitable capacity can be kept in first-class operating condition without shutting down the plant for repairs, by alternately overhauling one unit and then the other in the winter months.

Design of Building—Since the combustion units constitute the heart of the plant, the design of the structure to house them is subordinated thereto. The building should conform in shape and in interior layout to the design of the combustion units and to the plan which will freely permit of the most expeditious delivery, charging and handling

of material before and after combustion. The general construction should be substantial and fire-proof. The building should be well lighted and well ventilated, and all reasonable provisions should be made for the comfort of the men employed at the plant. The building is in the industrial class, and there is no reason, in this enlightened age, why the architectural design should not frankly express the purpose of the plant.

Appurtenances — Provisions for the handling and possible storage of ashes, and baling presses for tin cans are minor appurtenances which facilitate keeping the plant and surroundings orderly and presentable.

Storage of Garbage and Rubbish—If a plant is properly designed to take care of peak loads in an 8 to 10 hour charging and burning period, and with a reasonable allowance of excess capacity for anticipated growth of the community, there should be little or no necessity for storage space. The sooner garbage is burned after its collection, the better it is for all concerned. It will be recalled that it was the odors given off from decomposing garbage on scows, more than the odors from the plant itself, that discredited and brought about the abandonment of the garbage reduction process which was on trial at Staten Island. Garbage, left to itself, breaks down quite rapidly. Volatile and highly inflammable alcohols and esters are among the products of the spontaneous fermentation of garbage. Rubbish itself is a fuel and, once ignited, burns with great rapidity due to its loose texture and voluminous air pockets.

If storage bins are necessary to provide for conditions which cannot be foreseen, the greatest care should be exercised in their design and location.

Costs—"Assuming a construction cost of $1,000. per ton of capacity, and interest and depreciation to amount to 10%, the fixed charges would be about 32 cents per ton." This statement will be found in the standard work on the "Collection and Disposal of Municipal Refuse" written by Hering and Greeley in 1921, and it holds true today. How much less than $1,000. per ton of capacity may be paid for a modern incinerator will depend on the simplicity of the building and on moderation in the specification of mechanical appurtenances. Elaboration in architectural design and in mechanical devices as well as the inclusion in the contract of extras not properly a part of an incinerator plant, such as garages and machine shops, tend to run the first cost into figures well in excess of $1,000. per ton of capacity.

Operating costs—The main item is labor. The labor requirements for different plants are variously given as from a fraction of a man-hour to 1.4 man-hours. One man-hour per ton of refuse burned is a safe working basis, although wide variations in load factor or in operating conditions may shift this figure one way or the other. With labor at $5.00 per day of 8 hours and continuous 8 hour operation, this would amount to about 63 cents per ton of refuse burned, which together with a fixed charge of 32 cents per ton of capacity would bring the operating charges to about $1.59 per ton of material burned, bearing in mind that capacities are rated in tons per 24 hours.

Utilization of Waste Heat—In the general run of refuse incinerators there is considerable heat carried away with the stack gases and in the clinker and ash; the same is true of many industrial plants. This waste heat has been used successfully in Europe and Canada and to a certain extent in this country for the generation of steam. The steam thus generated may be used for other purposes around the plant. If it is decided to include utilization of waste heat in an incinerator project, provision should be made in the plans for the proper placing of a waste heat boiler and appurtenances. It is well, however, not to build any fanciful illusions as to the value or the availability of the steam generated. The load in refuse incinerators varies much more greatly than the load in industrial operations. The peak load occurs in summer when there is the least demand for power for lighting and heating purposes. Not only the seasonal load but the daily and hourly load are quite variable. If steam is generated in variable quantities at times when there is the least demand for it, the question arises as to means of harnessing the steam and converting it into some useful form of energy which can be stored for use when needed. That problem has not been solved. The equipment to harness steam and convert it into electrical energy is standard power plant equipment. It is well to bear in mind that the cost of such equipment properly proportioned for the utilization of waste heat recoverable as steam will run into figures exceeding the first cost of the incinerator plant. The utilization of the waste heat from refuse incinerators is an extremely interesting subject for speculation but likewise one which has not been fruitful in useful return.

Conclusion—I have tried to outline to you the fundamental principles underlying the practical incineration of refuse, especially garbage and rubbish. The fundamentals of furnace design, suggestions for plant location, first costs and operating costs as reflected by prevailing practice have also been touched upon. Endless elaboration along theoretical and technical lines is possible. I believe, however, that the fundamentals will serve as a safe and sound guide in the consideration of incinerator projects, and if they are followed and applied with common sense an eminently satisfactory result will be obtained.

ENDEMIC PURPURIC MENINGOCOCCUS BACTEREMIA IN EARLY LIFE, THE DIAGNOSTIC VALUE OF SMEARS FROM THE PURPURIC LESIONS*

By STAFFORD McLEAN, M.D., NEW YORK, N. Y.

DR. McLEAN presented a series of lantern slides showing abstracts of case histories of Endemic Purpuric Meningococcus Bacteremia in early life, and stressed the diagnostic value of smears from purpuric lesions. Of the patients admitted to the Babies' Hospital, with meningococcal infections there were purpuric eruptions in approximately 11 per cent. The youngest of these cases was 46 days of age and the oldest was 7 1-3 years. The face and extremities were areas of election for the hemorrhagic eruption. The practical value of stab punctures of the purpuric lesions was emphasized as an aid to early diagnosis. The advantage of this method of making an immediate diagnosis as opposed to culture of the blood was discussed. In 17 cases in which an effort was made to find meningococci in the hemorrhagic skin lesions in the disease, organisms were discovered in 12. One case report illustrated the usefulness of the smear from the purpuric lesion in the bacteriologic diagnosis. In this example with inflammatory changes in the cerebrospinal fluid the blood culture was negative, and both culture and smear from the cerebrospinal fluid failed to disclose meningococci. The only positive bacteriologic finding was the smear from the purpuric lesion. The simplicity of the technique of examining purpuric skin lesions for meningococci was described, and mention was made of the fact that only when the meningococci were found intracellularly was the result of the examination considered positive, although extracellular meningococci are of considerable collateral interest and may be significant. Positive smears of the organisms were found both in the early and late stages of the purpuric manifestations. Case reports were shown of meningococcemia without meningitis and in meningococcemia with early meningitis. The clinical picture associated with purpura in childhood was described, and emphasis was laid on the higher incidence of the fulminating type of case in the eruptive types of meningococcus bacteremia as opposed to the more common examples of meningococcus meningitis.

Autopsy protocols were presented and the possible relationship between suprarenal hemorrhage and early death in the fulminating cases was discussed.

The high percentage of the classic autopsy picture of status thymico lymphaticus in the rapidly fatal cases of meningococcus bacteremia was demonstrated, but this picture was not believed by the author to explain the early death in certain of these cases.

In conclusion, it was stated that examination of smears from the purpuric skin lesions in meningococcus bacteremia in early life offers a rapid, exact and consistent method for immediate bacteriologic diagnosis.

* A lantern slide demonstration given at the Annual Meeting of the Medical Society of the State of New York, Pediatric Section, at Rochester, N. Y., June 4, 1930.

LOBAR PNEUMONIA COMPLICATED BY ATELECTASIS IN A CHILD WITH COMPLETE SITUS INVERSUS

By MORRIS GLEICH, M.D., NEW YORK, N. Y.
From the Pediatric Department, Harlem Hospital.

N. W. colored, seven years old, took sick suddenly. Five days before admission he had fever, a blood-tinged sputum, dyspnoea, a pain in right chest and an expiratory grunt.

He was acutely ill. There was dyspnoea, an expiratory grunt, and the right chest did not move on inspiration. The right rib spaces were narnower than the left. The entire right chest anteriorly from apex to base was dull or flat, tender and gave no voice or breath sounds. A few scattered rales could be heard at times. Posteriorly, the apex and scapular regions were flat or percussion and the breath and voice sounds were absent. At the right base posteriorly, there were dulness with bronchial breathing and voice sounds and some crepitant rales. The left lung revealed exaggerated vesicular breathing with a hyperresonant percussion note, indicative of a compensatory condition.

The heart sounds were more prominent on the right side. The apex beat was heard best on the right side, five c.m. to the right of the right border of the sternum.

The x-ray and fluoroscope revealed the stomach on the right and the liver on the left side. A dextro-cardia was also seen with apex pointing to the right. There was an homogeneous clouding of the entire right pulmonary field. No foreign body was seen. Atelectasis was the impression. (See Plates 1 and 2.)

The electrocardiographic report showed a

rhythm which was regular and of sinus origin. The P and T waves were inverted in lead one. R was greater than S in lead three. S was greater than R in lead one. Those findings were characteristic of a congenital dextrocardia.

Von-Pirquet, Mantoux and Kahn tests were negative. Bronchoscopic examinations done two weeks apart, showed tissues which were pale and ischaemic, due to pressure from without or an exudate. No signs of foreign body or granulation tissue were present.

Chest taps and fluoroscopic examinations in various positions failed to reveal a foreign body or fluid. His temperature varied between 99-102 F for three weeks. Since then it has been

Plate 1. Complete atelectasis of entire right lung. The entire right chest ant. and post was dull or flat on percussion and gave no voice or breath sounds, except posteriorly, where there were bronchial voice and breath sounds and some crepitant rales (at the base)

normal. There were no chills, sweats or fetid sputum.

On several occasions, over a period of six weeks, bronchial breath and voice sounds could be heard over the right chest anteriorly, in the apical and infra-clavicular regions. Various rales and variations in the percussion note and voice and breath sounds could be heard all over the chest from day to day. These signs were due to increased or diminished amounts of air in the atelectatic lung.

X-ray taken eight weeks after admission, revealed normal right apical and infra-clavicular spaces. Here the percussion note, voice and breath sounds were normal. The upper lobe was completely aerated. The lower lobe was dull on percussion, with diminished voice and breath sounds and a few coarse rales. Here, X-ray showed a fluid level, a dense homogeneous shadow interpreted as pneumonia, and an area about the size

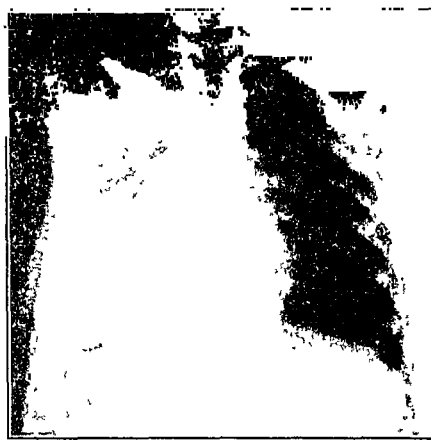

Plate 2 Three weeks later. Right apex and intercostal spaces are clearing, improvement in physical signs are noted. Apex of heart is seen pointing downward and to the right.

of a hazel nut, considered by some as pneumothorax and by others as an aputrid abscess cavity.

Twelve weeks after admission the physical signs in both lungs were almost normal. The x-ray showed a slight cloud at the right base posteriorly. There was some dulness here, with diminished voice and breath sounds and a few sonorous and subcrepitant rales. The patient sat up, ate well, and had neither cough nor fever. One week later he was out of bed.

Comment. This case presented several important considerations. One possibility was a right base pneumonia, complicated by an atelectasis due to a (ball-valve) plug of mucus in a bronchus. Another idea, in spite of negative bronchoscopic findings, was a foreign body in a bronchus. with associated cough, fever, pain and atelectasis. Gradually this foreign body was absorbed. A third thought concerned the abnormal position of the heart. Granted a pneumonic process, the dextro-cardiac causing mechanical pressure on a lobe of lung or bronchus produced the atelectasis. As the pneumonia resolved, the cardiac pressure, no longer operative, the atelectasis cleared.

EPILEPSY—CLINICAL AND DIAGNOSTIC PHASES

By E. M. JOSEPHSON, M.D., NEW YORK CITY, and MAX M. TEPLITZ, M.D., BROOKLYN, N. Y.

Though there have appeared in the recent literature many studies and speculations on the vascular phases of epilepsy, there has been little emphasized, certain phases of the disease which have come to be regarded by us as of deep significance. This article is in part based upon studies made by one of us (Josephson) over a period of several months at the New Jersey State Village for Epileptics, and certain aspects of it have been checked up recently by both of us.

Careful observations of numerous patients in generalized epileptic seizures of the grand mal type, but not including the Jacksonian type, have shown that during the tonic period of the seizure the heart muscle is involved in the tonic contraction to such extent that no heart sounds can be observed. At the same time, the peripheral pulses are not palpable. So constant has this finding been, that one of us has used it on several occasions, with success, in detecting malingering of epilepsy.

Ensuing upon the heart spasm of the tonic stage of the seizure, there develops dilatation of the right side of the heart, and with regularity, an acute edema of the lungs which is usually of a very transitory nature. The frothing at the mouth, which is a regular sequel of the grand mal seizure, is but a manifestation of this transient pulmonary edema. Examination elicits coarse, bubbling rales throughout the chest, especially at the bases, dullness at the bases posteriorly, and feeble breathing. These signs clear up with more or less rapidity, as the patients expectorate volumes of frothy sputum.

Speculating as to whether vascular changes are a secondary manifestation of epilepsy, or whether they may be primary in nature, a number of tests were undertaken. Blood pressure and pulse rate were compared before and after seizures, as well as in the intervals between seizures; but no constant or significant changes were observed, excepting in cases with associated cardiac disease. Attempts were then made to induce epileptic seizures. In a large number of cases it was found possible to induce seizures by more or less prolonged pressure upon the carotid arteries. In this connection it may be interesting to note that seizures were also induced in some cases of chronic progressive deafness, in which there was evidence of the deafness constituting an early symptom of brain tumor, as manifested by associated impairment of vision and limitation of color fields, altered reflexes, etc. Even more frequently, it was found possible, recently, to induce epileptic seizures in the patients by positive galvanization of the cranial contents, with the electrodes applied in various manners. But following negative galvanization of the cranial contents, it has been found to be difficult to induce seizures by pressure on the carotid arteries. This suggests a possible mode of palliative therapy.

The effects of galvanization upon the cranial contents may be surmised from the findings which one of us (Josephson) has made of its effects on the ear and eye. The variations in vascularity of the eye induced by galvanization of the cranial contents have been demonstrated and photographed, especially readily in cases with vision and vascularity impaired by disease. Negative galvanization induces dilatation of the eyeground vessels and an improvement in vision; whereas positive galvanization induces contraction of the vessels and a loss of vision. These effects are reversible. This makes it apparent that the function of the nerve tissue of the eye, and probably of other nerve tissue, is dependent upon vascularity and nutrition.

These tests seem to possess interesting possibilities in the diagnosis of epilepsy and latent brain lesions, especially in the very important field of industrial examinations; for it cannot be questioned that epileptic seizures in unsuspected cases are accountable for many train wrecks, transportation accidents, and industrial accidents; and any test which will enable the diagnosis of epilepsy in the absence of spontaneous seizures will add to public safety. At any event, these studies bear out the view that the fundamental pathology of the epileptic seizure is impairment of the vascularity of cerebral tissues.

HEREDITARY HEMORRHAGIC TELANGIECTASIA
A REPORT OF TWO CASES

By H. MASON HICKS, M D, AND ELIZABETH KNOX, M D, NEW YORK, N. Y
From the First (Columbia) Medical Division of Bellevue Hospital, New York

HEREDITARY hemorrhagic telangiectasia is a disease characterized by the presence of telangiectases on the skin or mucous membranes, by severe epistaxis and by the history of similar conditions in other members of the family

In 1921, Goldstein,[1] in a comprehensive article, reviewed the literature on this rare disease The first case was reported by Legg in the Lancet for 1876, and other early contributions to the subject were made by Chiari in 1887 and by Osler in 1901 From 1876 to 1921, Goldstein could find only 30 families reported in the literature and he added one family in which eleven members were affected By 1921, the disease entity had been well established and Goldstein includes in his summary of the case reports only those cases in which the three essential factors were present, namely, telangiectases, epistaxis, and family history

Since 1921, scattered reports of similar cases have appeared We have been stimulated to review these reports by the recent admission to the wards of the First Medical Division of Bellevue Hospital of two cases of hereditary hemorrhagic telangiectasia A brief survey of the literature and a report of these cases follow

In 1921, after Goldstein's article appeared, Freudenthal[2] reported a typical case of a 55 year old man with epistaxis of 12 years' duration, and many telangiectases, whose mother, brother and sister also had nose bleeds, though the telangiectasis was doubtful In a number of cases, it is impossible to establish the presence of telangiectases in other members of the family It is usually considered sufficient if a definite history of nose bleeds is obtained

The next case report was by Fitzhugh,[3] of Philadelphia The patient in this case was a woman 37 years old The mother, a brother and a sister had had frequent severe epistaxis, as did the patient In addition, the patient had many telangiectases Fitzhugh emphasized the factor of atavism to explain certain otherwise typical cases in which no hereditary factor could be established Such a case was reported by Miller[4] in 1923, in which bleeding from the nose and telangiectasis were both present, but careful inquiry failed to elicit any history of epistaxis in the family

In 1925, Arrak[5] reported two cases from Germany The first of these was a man, 55, whose father and four brothers also had epistaxis The second was a woman, 49, whose brother and maternal aunt had typical telangiectases and epistaxis This patient's daughter had telangiectasis but no epistaxis However, she had had several unexplained pulmonary hemorrhages No cause for these could be found on repeated physical examinations and x-rays of her chest This case is of interest in view of a series of cases of familial hemoptysis reported by Libman and Ottenberg[6] Also in 1925, Schwartz[7] reported a case of a woman, 49 who not only had epistaxis but also had severe hemorrhages from the tip of her tongue where there were numerous telangiectatic areas The patient's mother had died of an uncontrollable nasal hemorrhage No other member of the family gave a history of epistaxis

In 1926, P E. Weil[8] reported two cases from France The first case was a woman, 36 years of age, in whom telangiectases developed at the age of 6 Epistaxis occurred later A mother, brother, sister and aunt all had telangiectases but no epistaxis Her maternal grandfather had frequent severe epistaxis The second case was of a woman 43 years of age, in whom telangiectasis and epistaxis were present The epistaxis began at the age of 4 Her paternal grandfather died of a nasal hemorrhage Her father had epistaxis but no telangiectases A brother and two sisters had telangiectasis, as did also a paternal uncle and his daughter In the same year, Williams[9] reported two cases from the New York Skin and Cancer Hospital The first of these was a woman, age 56, whose father and brother also had both telangiectasia and epistaxis However, 12 other brothers and sisters were unaffected and so far her own children have not shown the condition The second case is interesting as being one of the few reported in a child This is the case of a young boy of 10 with several small nevi on the face and no epistaxis, but whose mother, two brothers and maternal grandmother had the typical condition Also in 1926, East[10] reported 3 cases One family had 11 members affected, the second 15, and the last only 2 In this large number of persons, he points out the interesting fact that the great majority either developed the telangiectases at about the age of 20, or at least noticed them at that age

In 1927, Mekie[11] reported a family in which 9 members were affected and the usual age of onset in this family was 15 The patient, a man of 38, had first noticed the telangiectases on his face at the age of 15, and the epistaxis began several years later Also in 1927, Mackay and McKenty[12] reported a family from Winnipeg in which 5 members were affected The patient was a woman, 44, who had had epistaxis for 12 years, but who had only noticed the telangiectases for two years before admission to the hospital

In the same year, Balph[13] reported the case of a woman, age 54, with typical telangiectasis and epistaxis, whose mother, maternal uncle, sister and three nieces were similarly affected. In his study of this family, Balph found that though the epistaxis began in early childhood, the telangiectases did not appear until 20 to 30 years of age, and that the symptoms began to be more severe in middle life.

In 1928, Foggie[14] reported a most interesting case from Edinburgh of a woman who had a few telangiectases and an occasional nose-bleed, but whose predominating symptom was painless hematuria, with no other urinary findings. Twelve members of her family, however, had both marked telangiectases and frequent epistaxis. This case is particularly interesting in the light of the cases which have been reported of familial hematuria. No other members of this family had hematuria. Also in 1928, Flandin and Soulie[15] reported from France the case of a woman of 34, with very severe epistaxis and many telangiectases present since early youth. Five other members of the family were affected. In the same year Thomson and Lamb[16] reported a case of a woman, 30, who had had almost daily epistaxis for 15 years. Numerous telangiectases were present. Four other members of the family were affected.

In 1929, Erdheim[17] reported a most interesting family in which 16 members out of 53 were affected. Six of these he personally examined and found telangiectases and elicited the history of epistaxis. In the same year, Harper[18] reported the case of a man, age 45, who had had severe and frequent epistaxis for as long as he could remember but only noticed the telangiectases about 5 years before admission to the hospital. An interesting point in this case is that tarry stools had been noticed several times without any cause for bleeding found in the gastro-intestinal tract. Eight other members of this family were affected.

Goldstein found thirty families reported in the literature and added one more of his own. Since then, we find reports of 19 more families, making a total number of families previously reported 50. The disease is transmitted by both men and women. In most cases the telangiectases are not noted until 15 or 20 years of age, but the epistaxis is frequently present from childhood. The condition usually becomes more marked in middle life.

Case 1. D. C., an Italian male, aged 42, single, was admitted to Bellevue Hospital on November 19, 1929, complaining of severe epistaxis of 6 days' duration. The patient gave a history of nose-bleeds since early childhood. These had occurred more frequently and been more severe during the past two years. He had been admitted to various hospitals during this period for the control of the epistaxis. There was no history of alcoholism, syphilis, or other diseases.

The patient's brother, aged 41, bleeds occasionally from the nose, and has telangiectases on lips, edges of tongue, and conjunctivae. One sister has frequent nose-bleeds. Three other brothers and one sister do not bleed. His father and paternal uncle give a history of epistaxis. The paternal grandmother gave a similar history. The patient's brother and sister each have three children, none of whom bleed.

Physical examination revealed a well developed, poorly nourished man. The skin had a faint yellow tinge but the sclerae were not jaundiced. Lips and mucous membranes were extremely pale. There were numerous minute telangiectatic areas on the lips, edges of tongue, and on the nail beds. The conjunctivae were clear. Fundi were negative. The nares were filled with dried blood. There were no telangiectases on the face or body. Examination of the larynx was negative. The heart and lungs were negative. The edge of the liver was felt two cm. below the costal margin. The spleen was not palpable. There was no lymphadenopathy.

Urine—Amber; alkaline; a faint trace of albumin; sugar negative; few white blood cells and no casts.

Blood—R. B. C. 1,800,000; W. B. C. 8,400; Hgb. 15 per cent (Dare); Polymorphonuclears 78 per cent, Transitionals 3 per cent, Lymphocytes 16 per cent, Eosinophiles 2 per cent, Basophiles 1 per cent. The blood picture was that of a secondary anemia. No abnormal cells were seen. Bleeding and clotting time were normal. The clot retraction was normal. Platelets—200,000. Blood pressure, systolic 110, diastolic 65. Blood Wassermann negative. Blood chemistry—NPN 33 mg. per 100 cc. Sugar 80 mg. per 100 cc.

Course—Patient was transfused on day of admission and the nose was packed. On removal of packing three days later, the bleeding recommenced. Two tubes, each containing 25 mg. of radium, were inserted in each side of nose and nares were packed with iodoform gauze. This was allowed to remain for 24 hours. Since then the bleeding has been much less frequent and less severe.

A month later he began passing bloody stools. Examination revealed a prolapsed rectum and a few small external hemorrhoids. Proctoscopy showed no telangiectases.

At the present time, 4 months after admission, he is having only occasional slight epistaxis. He has had an operation for hemorrhoids and has had no more blood in his stools.

Case 2. J. C., a German male, aged 55, married, was admitted to Bellevue Hospital February 13, 1930, suffering from acute cardiac decompensation. Physical examination revealed a pale, middle-aged white man, extremely dyspneic and

orthopneic, coughing up frothy sputum The nares were filled with dried blood The lips, tip of tongue, soft palate and nail beds showed numerous small telangiectatic areas Laryngoscopic examination showed telangiectatic areas over the left arytenoid There were many sibilant and moist rales throughout both lungs The heart percussed enlarged both to the right and left and there was increased dullness over the base The rate was rapid and regular The aortic second sound was louder than the pulmonic second There was a soft systolic murmur at apex and at the aortic area A higher pitched systolic was heard over the tricuspid area The pulse was rapid and thready Abdomen was negative There was slight pitting edema of lower extremities Moderate clubbing of fingers There was no lymphadenopathy

Diagnosis of familial telangiectases, secondary anemia, cardiac dilatation and myocardial insufficiency was made

The history revealed that the patient had had nose bleeds since early childhood These had increased in frequency and severity The patient's mother had severe nose bleeds and a brother of the patient gave a similar history Of the patient's two children, one son has frequent epistaxis

Blood—R B C 3,100,000, Hgb 35% (Dare), W B C 16 600, Polymorphonuclears 72%, Lymphocytes 21%, Transitionals 7% The platelet count was within normal limits The blood smear was that of a secondary anemia No abnormal cells were seen Blood Pressure—systolic 140, diastolic 75 Blood Wasserman negative

Course—The patient compensated rapidly, and during his stay in the hospital he had only an occasional slight epistaxis He refused further examinations and treatment and was discharged five days after admission

Summary

1 Since Goldstein's paper in 1921 in which he found 30 families reported in the literature and added one more of his own, 19 cases have been reported, making a total of 50 families

2 Two additional cases are presented

UROLOGY IN CHILDREN*

By FREDERICK J PARMENTER, M D, F A C S, BUFFALO, N Y

RECENT perfection of infant cystoscopes now offers the same opportunity for accurate diagnosis in children which has been possible in the adult for many years past

These instruments range from 12Fr caliber to 18Fr, which permits of both observation and catheterization of the ureters, so that no child, no matter how small, need be denied a proper urological study when necessary

The diseases of the urinary tract found in children are the same as those found in older individuals with the added possibilities of many more congenital anomalies being encountered, which if of an obstructive nature, may cause death before adult life is reached These obstructions, if associated with infection, present a most seri-

* Read at the Staff meeting of the Children's Hospital Buffalo N Y February 10 1931

ous complication, inasmuch as proper drainage is necessary before recovery is possible.

It is true that the majority of cystoscopic examinations, especially in young children, and more so in males, will have to be carried out under general anesthesia. The period of anesthesia, however, need not be any longer than the time necessary to pass the cystoscope and catheterize the ureters—about five minutes. The anesthetic may then be stopped, and the dye used in estimating renal function, injected before the patient has recovered consciousness. There remains then but to take *x*-rays and make pyelograms, if the latter are considered necessary.

The commoner urological lesions which cause patients to bring their children to the doctor are:

1. Renal infections which cause temperature, pain over the kidney when the child is handled and the area pressed upon, pyuria with frequency and dysuria. Swelling over the kidney may be present.
2. Difficulty and dysuria where the urine is passed drop by drop, with the child straining enough at times to become purple in the face, and associated with evident pain. Some children will deliberately hold the urine for long periods to escape the pain caused by voiding.
3. Congenital defects of the external genitals as abnormalities in the opening of the urethra, constant wetting from a ureter which opens in the vagina or perineum instead of the bladder, extrophy, undescended testes, incontinence from concealed spinal bifida or some other cord lesion.
4. Functional nocturnal enuresis or diurnal enuresis.

Renal infections may be Non-Tubercular or Tubercular. Their location may be the cortex or medulla of the kidney, and the process may be a localized or diffuse one. Selectivity of the coccus infections for the cortex and the bacillus group for the medulla was suggested by Cabot and Crabtree in 1917, and their observations in the main are true, though of course exceptions occur in many instances.

The early symptoms of the coccus group are temperature, prostration, local pain or tenderness over the kidney, with swelling if perinephretic abscess develops or the kidney becomes greatly swollen. The urine may be clear and no urinary symptoms present. If cystoscopy, *x*-ray and pyelography are carried out, the results will be negative, as early there is no communication with the collecting tubules and pelvis.

The bacillus group presents identical symptoms with the exception that pyuria and bladder symptoms are present from the onset and, indeed, may precede the others. Cystoscopy shows pus from the affected side, reduced kidney function; pyelography, a dilated kidney pelvis and ureter. Cystoscopy is rarely indicated during the acute process. Females form the majority suffering from this infection; while coccus infections, in the writer's experience, are about equally divided between the sexes.

The pathological picture in the coccus infection is a localized or diffuse collection of abscesses ranging from pin-point to larger, depending upon the duration of the process. Perinephretic abscess may occur with practically no evidence of kidney damage, or if localized, a typical carbuncle may form containing in time as much as two or more ounces of pus.

The bacillus group shows cloudy swelling of the collecting tubules, calyces and pelvis with secondary infection of the ureter and bladder. As pus in the kidney parenchyma rarely forms and the majority recover or become chronic, surgery is rarely indicated during the acute process so that but few specimens are available for pathological study.

Mixed infections are common if the process does not undergo resolution in a short time or the condition becomes chronic.

Chronic infections are characterized by constant pyuria associated with frequency and urgency, which may be severe enough to cause incontinence. Acute exacerbations of fever, pain, etc., are common and if repeated almost certainly point to the flare-up of a chronic process.

As many of the coccus infections undergo pus formation some form of surgery will usually be necessary, varying from drainage of a perinephretic abscess or a localized collection of pus in the kidney, to nephrectomy. Mild infections do recover in many instances upon expectant treatment. The bacillus group almost invariably recover if unilateral upon mild alkalization of the urine, forced fluids, glucose in the vein and salt solution under the skin. Urinary antiseptics are of little use in the acute infections as they are largely diluted by the amount of fluids which should be given and are therefore reserved for the chronic cases, where fluids can be restricted. Should a bacillus infection not disappear in two weeks, complications, as stone or some congenital obstruction, should be considered and an *x*-ray taken, which if negative demands a urological study of the patient. If these measures are carried out, much embarrassment may be saved the physician later and a kidney preserved.

Tuberculosis may be cortical or medullary. If the former, the lesion may heal or gradually spread, destroying the kidney through autonephrectomy, form a perinephretic abscess, or become cortico-medullary, which frequently happens. Naturally a healed cortical lesion will cause no symptoms. A perinephretic abscess results in a slowly increasing swelling over the kidney area with the signs of a very low-grade infection. The medullary and cortico-medullary types early are characterized by frequency, dysuria and pyuria with nothing else to suggest the nature of the condition, and unless a considerable pyonephrosis exists, abdominal palpation will reveal nothing.

In the majority of cases cystoscopy alone determines which kidney is involved in the majority of these cases are unilateral by the time the condition is recognized and if a bilateral lesion had existed, healing has taken place upon one side

Tubercle bacilli are readily demonstrated in the bladder and ureteral urines If unilateral, the treatment is nephrectomy after the child has been brought into the best possible physical condition, even if this takes months of treatment, and the same is true of the post operative care If these measures are not followed the results of surgery are much more apt to be disappointing

Naturally any infection in the kidneys may be uni or bi-lateral, which emphasizes the necessity for a proper study before any surgical procedure, especially nephrectomy, is carried out, because silent infections do exist and have been found when least expected Nephrectomy in these cases would promptly result in death

Kidney stone will often be overlooked if infection or hematuria from irritation does not occur Many will be found in routine x ray examination taken for other purposes Stones may occur in one or both kidneys Pure uric acid or cystin calculi fail to show upon the x ray plate They are rare

Calculi should usually be removed to prevent kidney damage from back pressure and interstitial changes from irritation If not so treated many nephrectomies will be necessary later because of destroyed organs

Tumors will be discovered by the occurrence of a symptomless hematuria or the finding of a mass over the kidney, when the growth has attained sufficient size, and confirmed by urological examination

Congenital anomalies of the kidneys as abnormal vessel, ureteral stricture, dystocia etc which cause partial obstruction produce a slow progressive hydronephrosis with complete destruction in time The process is so slow little or no pain may be present Finally, a swelling over the kidney appears No other symptoms are present save pain, which may be so slight that it passes unrecognized An early diagnosis is possible only through a urological study, therefore pain over the kidney should not be neglected as it is the only symptom

Difficulty of urination is due to obstruction at the vesical neck The common causes in children are Bladder stone, foreign body or diverticulum In the urethra Congenital or traumatic stricture, valves in the posterior portion phimosis etc

The symptoms have already been mentioned as difficulty, straining and dribbling to actual incontinence

If the condition is chronic, as valves in the urethra the resulting kidney back pressure may result in toxic symptoms where the individual suffers from nausea and vomiting loss of weight and strength secondary anemia and the other signs of uremia Many of these cases are treated as difficult feeding or malnutrition is there is little to direct attention to the urinary tract However these children are usually incontinent from bladder overflow and abdominal palpation will reveal the distended bladder Rectal examination will show a full bladder filling the pelvis, and a funnel shaped projection, which is the dilated urethra and vesical neck, extending from the bladder to the point of obstruction in the urethra A catheter introduced may or may not encounter an obstruction However, residual urine is present, and the distended bladder disappears The distended bladder should be decompressed as in the prostatic and the patient properly prepared for operation, because only the rupture of the valve relieving the obstruction can result in cure and saving the child's life This is usually done through a suprapubic incision The end result of neglected cases is double hydronephrosis with destruction of renal parenchyma, uremia and death

Incontinence may be true or false and means absolute loss of urinary control The former occurs in spinal bifida or some other loss of spinal nerve control The rectal sphincter is also involved and an x ray will show the bony defect in spinal bifida There is also a saddle shaped area of anesthesia around the anus and perineum Absence of bladder sphincter as in extrophy, is another example of true incontinence

False incontinence comes from an overdistended bladder due to chronic obstruction, from irritation of the bladder by infection, stone, foreign body and true enuresis

Enuresis from a too strong detrusor muscle, is aggravated by a number of causes and the treatment outlined years ago by a Boston physician, whose name escapes the writer, has been so successful that it is copied verbatim The treatment for all of these conditions depends upon removing the cause when possible which means an accurate diagnosis

Treatment of Enuresis

1 All foods forbidden between meals, even milk and bread and butter
2 Diet list Milk butter, eggs, meats, fish, breadstuffs, cooked cereals, macaroni vegetables, oranges, stewed fruits and simple, unsweetened desserts
3 Exclude the following foods Soups coffee, tea cocoa sweet and salty and highly seasoned foods, ice cream, candy, pastry, cake, jellies, jams etc, condiments bananas and raw apples Meats, eggs and vegetables forbidden for supper to make it easy for the digestive system
4 Child to be in bed by 7 P M If very nervous, school is prohibited temporarily, and a nap re

quired in the afternoon. No play after 4 P.M. Child to be entertained by toys and books in a chair. Moving picture shows, music lessons and evening home lessons prohibited.

5. Habits: No fluids after 4 P.M.

Regular hours for urination at night, namely, 7 P.M. on going to bed, 10 P.M., and not again until 6 A.M. If child cannot go eight hours, it should urinate at 2 A.M. After a few weeks the voiding at 2 A.M. can be omitted. Punctuality is of prime importance.

Day wetters to urinate at regular intervals from three hours during the day to every twenty minutes. Interval gradually lengthened.

This in a brief way covers a few of the important problems involving the urinary tract of infants and children which confronts the pediatrician, where consultation with the Department of Urology will aid in establishing a diagnosis.

In closing, a word upon the place of uroselectan in the field of urological diagnosis:

Uroselectan contains a high iodine content, which permits visualization of the urinary tract when administered intravenously. In normal conditions, the drug passes through the kidneys and is eliminated in the urine, so that it is also a test of renal function in a way. At times the elimination is so rapid that the shadow cast is a very faint one, and the outline of the pelvis and ureters difficult to read. If no kidney function remains, there is of course no shadow. The best pictures are obtained in kidneys which still possess some function associated with an incomplete obstruction. Stones may be obscured by the density of the medium, so that a plain plate should always be made before the drug is introduced or a retrograde pyelogram is made. Uroselectan plates must be properly interpreted, which means some considerable experience upon the part of the examiner. Finally, the diagnosis must not rest alone upon the *x*-ray, but by the study of separate urines, the history, and physical examination, otherwise disastrous mistakes will be common. Uroselectan has its place and at times is invaluable. However, the consensus of opinion at present is, that it cannot take the place of the cystoscope and ureteral catheter as a routine method of diagnosis. It should be used where cystoscopy and ureteral catheterization is impossible or contraindicated by the condition of the patient.

SECONDARY ANEMIA ASSOCIATED WITH DIAPHRAGMATIC HERNIA*

By HARRY L. SEGAL, M.D., ROCHESTER, N. Y.

DIAPHRAGMATIC hernia is no longer the rare condition it was supposed to be before the advent of the roentgen ray, as is readily manifested by the increasing reports of cases appearing in recent years. It is taken into consideration more frequently in the differential diagnosis of certain abdominal and thoracic disorders. Its history, symptoms, complications, and treatment have been so amply reviewed that they will not be discussed here.

The purpose of this paper is to bring to attention one aspect of this condition that has received no special comment in the past, namely, secondary anemia. There are over 400 articles on diaphragmatic hernia, and only about 10 of these note anemia as one of its symptoms or complications. Crohn[1] states that an unusual form of secondary anemia of a marked nature may occasionally be observed in diaphragmatic hernia and that his attention was first called to this by Fineman. Hedblom[2] records that anemia was among the occasional symptoms observed in 229 cases. Bock[3] mentions three patients with diaphragmatic hernia complicated by bleeding and secondary anemia. Engels[4] and others record anemia as a finding in diaphragmatic hernia. None of these authors call attention to the fact that only symptoms of secondary anemia and nothing subjectively to point to the gastro-intestinal tract may be present.

Of four cases of diaphragmatic hernia at the Strong Memorial Hospital of the University of Rochester there were two patients in whom at one time symptoms only of secondary anemia were present and in whom, moreover, there was nothing in the physical findings to call attention to the gastro-intestinal tract or to diaphragmatic hernia. In the review of the literature there were found four similar cases, one of which was also studied at the Strong Memorial Hospital. Brief résumés of these reports have been tabulated under Group 1 in the table, and more detail histories of the two cases with secondary anemia studied at the University of Rochester Hospital are given later.

Besides those patients with symptoms only of secondary anemia there were others in whom the secondary anemia accompanied one or more symptoms related to the abnormality in the gastro-intestinal tract. These have been summarized under Group 2. There were many other cases in the literature in which it was stated that anemia was present or that the patient appeared to be anemic, but they were not abstracted as no laboratory findings were mentioned.

* From the Department of Medicine, University of Rochester, School of Medicine and Dentistry and the Medical Clinic of the Strong Memorial Hospital, Rochester, N. Y.

The cause of the anemia in diaphragmatic hernia, whether or not gastro-intestinal symptoms are present is almost always bleeding, although Southby[5] in his case considered malnutrition as the cause owing to the abnormal position of the stomach and the consequent poor digestion of food. That bleeding may occur is readily realized from the melena present in both of the patients reported here, in the cases mentioned by Bock,[3] and in other reports in which hematemesis, melena, or both are recorded as findings.[6]

The cause of the bleeding may have been due, in some cases, to other conditions present coincidently, such as bleeding polyps, hemorrhoids, blood dyscrasias, and also ulcers not involved in the hernia. Such cases are exceptional, for the study of the patients reported in the literature, which have come to operation or autopsy, proves that bleeding is usually a direct result of the hernia. The following causes of such bleeding must be considered:

1. Passive congestion, as a result of the pressure on the veins as they pass through the narrow hiatus of the hernia, or by angulation of the veins caused by the change in position of the viscera.

2. Ulcer, which may be due to varicosities resulting from passive congestion, or as a result of disturbed arterial supply.

3. Inflammation, in the region of the wall of the viscera incarcerated in the hiatus of the hernia.

Crohn[1] states that the seepage of blood is from the effect of pressure of the diaphragm upon the incarcerated gastric wall and particularly the gastric mucosa. Pancoast and Boles[7] say that hematemesis may occur and that it is due to inflammation in that part of the stomach wall involved in the opening. Morrison[8] records that Dr. Fiske Jones of Boston operated on several cases and found the margin of the hiatus thickened and the stomach wall showed more or less dense cicatrix-like thickening of that portion which had become herniated. This he interpretated as an inflammatory process which might account for the hematemesis. Von Bergman and Staehelin[9] believe that the loss of blood may be due to incarceration or ulcer. Kienbock[10] in a review of ulcers associated with diphragmatic hernia relates the cause of the ulcer to the hernia. He says that, as a result of pinching, angulation, and torsion of blood vessels, there is a disturbance in the circulation which results in impairment in the nutrition of the stomach wall and prepares the way for ulcer or incarceration and even for gangrene and perforation. Dubs[11] gives the same explanation for ulcer formation. Neugebauer[12] says that the hematemesis is due to ulceration resulting from venous stasis. Aue[13] offers it as his opinion that true ulcers may occur as a result of diphragmatic hernia in the following sequence; venous stasis, swelling of the mucosa, hemorrhagic erosion, and finally ulceration. Harrington[14] believes that traumatic ulceration may occur as a result of torsion and malposition of the stomach and according to his view these ulcers are superficial erosions and that they do not penetrate the wall of the stomach as do inflammatory ulcers. That ulcers do occur as a consequence of diaphragmatic hernia has also been shown by many other authors,[15] reporting cases which have come to operation or autopsy. Those cases with ulcers which do not seem to have resulted from the hernia have not been included.

Case Reports

Case 1, Miss E. S., age 64 was admitted to the Strong Memorial Hospital, Nov. 11, 1926 with complaints of anemia and weakness for 14 years. The symptoms came in attacks about once a year and consisted of weakness, dyspnea, and palpitation. For 9 years these were the only symptoms, but 5 years ago she had tarry stools and hemoptysis. The past history and system review revealed little of significance except the following; hysterectomy and appendectomy, 1918, automobile accident in 1921 at which time she fractured her tibia. The family history was irrelevant except that her brother had been operated upon for a diaphragmatic hernia.

Physical examination showed a short stout female adult of rather pale appearance. The heart was slightly enlarged to the left, and a precordial systolic murmur was present. Otherwise the physical examination revealed nothing unusual. B. P. 130/70.

Laboratory Findings—Hb. 65% Sahli, RBC 3,740,000, WBC 6750.

Differential — Polymorphonuclear leucocytes 82%, Lymphocytes 15%, Transitionals 2%, Eosinophiles 1%.

Wassermann reaction of the blood was negative.

Stools—Guaiac test for occult blood was positive.

Gastric analysis—Ewald test meal—Free hydrochloric acid 26 c.c. n/10 per 100 c.c. of gastric contents. Total acid 39 c.c. n/10 per 100 c.c. of gastric contents. Roentgenographic examination showed the cardiac portion of the stomach above the diaphragm. The duodenum was held down and considerable defect was noted on the lesser curvature. Duodenal ulcer could not be ruled out.

This patient had been studied previously at the Rochester General Hospital where the diagnosis of diaphragmatic hernia had also been made. Operation was performed in August, 1928, by Dr.

Fiske Jones of Boston who found a large diaphragmatic hernia, the hiatus of which admitted three fingers. The stomach and duodenum appeared normal.

Case 2. Mrs. Y. K., age 52 was admitted to the Strong Memorial Hospital, December 4, 1929 with a history of four weeks duration, previous to which time she was in good health. Her symptoms began suddenly on arising one morning when she felt weak, dizzy, and nervous. These symptoms persisted, and in addition she developed dyspnea and insomnia. Her past and family history were essentially irrelevant.

Physical examination revealed a short, rather stout Jewish woman whose skin was of a pale yellow tint. The sclera and mucous membranes were pale. The spine showed a scoliosis of the upper dorsal vertebræ to the left and the lower dorsal vertebræ to the right with a slight kyphosis. The right side of the chest was protuberant and the left side was sunken. There was slight impairment of the percussion note at the base of the right lung posteriorly. The heart was not enlarged to percussion and the sounds were of fair quality. The abdomen appeared normal. Vaginal examination revealed an enlarged uterus with several hard masses posteriorly (myomata). External hemorrhoidal tags were evident on rectal examination. Varicose veins were prominent on the left leg.

B. P. 134/78

Laboratory Findings—Hb. 50% Sahli, RBC 3,100,000, WBC 6,000.

Differential — Polymorphoneutrophiles 70%, Small Lymphocytes 28%, Transitionals 2%. The erythrocytes showed a slight poikilocytosis and anisocytosis.

Wassermann reaction of the blood was negative.

Stools—Guaiac test for occult blood was positive in repeated specimens.

Roentgenographic examination showed a herniation of the cardiac portion of the stomach through the esophageal hiatus.

On proctoscopic examination no bleeding points were seen in the rectum.

Comment

These two cases demonstrate that secondary anemia at one time may be the only symptom of diaphragmatic hernia. Without the aid of the roentgen ray the cause of the anemia would have remained unrecognized which emphasizes the importance of the roentgenographic examination in the diagnosis of such lesions of the gastro-intestinal tract.

Abstract of Cases of Secondary Anemia Associated With Diaphragmatic Hernia

Group	Case reported by	Sex	Age	Symptoms	Description of Hernia	Confirmed by	Occult Blood in Stools	Hb. %	RBC† mil.

	Southby (5)	M	2½	Pallor, weakness, anorexia, gurgling sounds in abdomen.	Almost entire stomach, portion of duodenum above diaphragm, hernial pouch in region of foramen for vena cava.	Autopsy.	Not reported	20	2, 8

Group 2 represents cases with both secondary anemia and gastro-intestinal symptoms.
†RBC mil. signifies the number of red blood cells in millions; thus 2, 5 means 2,500,000 red blood cells.

SUMMARY

Two cases of diaphragmatic hernia from the Strong Memorial Hospital of the University of Rochester and three cases from the literature, in which at one time the only symptoms present were those of secondary anemia, are briefly reviewed.

Five cases of diaphragmatic hernia, in which symptoms of secondary anemia accompanied gastro-intestinal symptoms, are also tabulated. The exact number of these patients could not be estimated as many of the cases reported had no blood findings stated, although melena, hematemesis, and even anemia were mentioned.

The anemia in both of the above groups of cases is usually due to loss of blood resulting from the effects of the hernia. A sufficient number of patients with diaphragmatic hernia and secondary anemia have come to operation or autopsy to prove that such is the case.

CONCLUSIONS

Secondary anemia may be associated with diaphragmatic hernia either alone or in addition to other symptoms of the hernia.

Loss of blood is usually the cause of the anemia and the loss of blood is usually due to pathological changes produced by the diaphragmatic hernia.

THE VALUE OF THE CANCER CLINIC TO THE COMMUNITY*

By WALTER L. MATTICK, M.D.

From the State Institute for the Study of Malignant Disease, Buffalo, N. Y., Burton T. Simpson, M.D., Director

CANCER morbidity and mortality are definitely on the increase. From 1910 to 1924 the cancer rate increased approximately 20% in the Registration Area of the United States and 29 per cent in the Commonwealth of Massachusetts. The present mortality rate for cancer is approximately 125 per 100,000 population. Thus 150,000 deaths may be expected from cancer in the United States in 1930 of which number about 5,000 will occur in the State of Massachusetts to which number the city of Brockton will contribute about 85 cases. If, in accordance with the assumption of the Society for Cancer Control, we multiply the above figures by three we will arrive at an approximation of the number of living cases of cancer to anticipate in 1930. Such a rate, while highest in the U. S., is followed closely by other states, especially New York and while almost astounding is only evidence of similar trends in all civilized countries. Hence a reason for the cancer clinic.

Besides showing indications of increase, cancer is also a disease failing to respect any persons or races. No economic or social status is exempt; it is equally a disease of rich and poor.

Cancer may occur at all ages from the cradle to the grave but its greatest incidence is after midlife. Thus of all men dying after 40 years of age, 1 out of 9 die of this disease, while correspondingly for women dying after this age period 1 out of every 6 or 7 deaths is due to this malady. The greater incidence in women is accounted for by the greater prevalence of cancer in the genital tract and breasts of this sex whereas amongst men cancer of the digestive tract leads in preference. It may be said with probabilities of assurance that every one living long enough would develop cancer. Thus the great strides in the betterment of living and economic conditions that have added so much to the eradication of infectious disease like tuberculosis and resulted in a material increase of the average longevity, has at the same time increased the expectancy of more individuals to live on to old age and hence to develop cancer. Thus we see malignancy predominatingly as a disease of old age, possibly a result of bodily degeneration, second only as a cause of death to heart disease and pneumonia which latter is mostly seasonal in prevalence.

You will naturally ask, what is the medical profession and state doing about these facts. I might add that practically every large state, university and hospital in our land is intently interested in cancer research in its many phases and has been for some time past. The chemist, the physicist, the biologist, the physiologist and all scientists have joined with the medical profession in a united effort. The work done has been enormous but it has chiefly led to enlightening us on the negative phase of cancer, i.e., what cancer is not.

We can now say with assurance that cancer, while an enigmatic disease, is not contagious or, infectious in the ordinary sense of the word. If this were not true then those specializing in this field would surely die of it. Truly, Doyen, Blumenthal, Nuzum and many others have attempted to isolate a cancer germ, but on critical investigation these have all failed to satisfy even the most credulous as a cause of this malady.

Cancer is not hereditary in the ordinary sense, the work of Sly on mice notwithstanding but a certain predisposition may be transmitted through inheritance.

What then is cancer? Well, so far as we know, cancer is a multiplication out of all reason and beyond all bounds of groups of the body cells which for want of a better expression we say have lost their tissue restraint. These cells are probably changed adult body cells which appear to have assumed the "embryonic" in their physiologic and biochemic propensities rather than embryonal cells per se. Thus cancer, according to Dr. Ewing, one of America's foremost workers on this disease, has been called "an autonomous new growth." The secret of this rapid growth of cells and the lack of normal tissue restraint that has so long baffled the research of ages probably resides in biochemic body changes.

We have long known of the role of chronic irritation in relation to cancer. Thus we have pipe smoker's cancer of the lip, cancer of the mouth in betal nut chewers of Malay, analine worker's cancer of the bladder, paraffin worker's cancer, chimney sweep's cancer of the scrotum, the Kangri stove cancer of Kashmir and mule spinner's cancer, etc. In fact, cancer can be produced experimentally in the stomach of rats by feeding with infested cock-roaches as shown by Febiger, cancer of the skin in mice by persistently painting the backs of the animals with a known carcinogenic grade of coal tar and sarcoma in the liver of rats by infesting with cysticercus as produced by Bullock and Curtis. Thus chronic irritation whether mechanical, thermal, chemical, actinic as *x*-ray or the result of chronic prolonged infections, is influential at least in determining the site of cancer in constitutionally predisposed individuals.

"Cancer a race against time." This is a common expression that is most assuredly true for this is a most insidious disease in onset, seldom

* Read at the opening exercises of the 12th State Cancer Clinic to be inaugurated by the Department of Health of Massachusetts, at Brockton, Massachusetts, June 12, 1930.

giving warning of its presence till late in its course and because of this insidious, painless onset with few or no inconveniencing symptoms, most patients put off consulting their physician till it is too late. In fact, 75 per cent of the patients coming to our clinic at Buffalo and other clinics in this country, come too late when hope of recovery has passed and when all that can reasonably be expected to achieve is alleviation of pain and suffering in the last days of their disease.

Thus the majority of patients delay 6 or 8 months after the appearance of the first warning before consulting their doctor. This, you see, is a sad commentary when we stop to consider that this is a disease with an average life expectancy without operation or treatment in all its forms of approximately two years at the best and often a much shorter period. Thus one-third of the life expectancy is immediately lost and the chances of recovery or increased expectancy beyond this period of two years have been materially decreased by procrastination "which is the thief of time," valuable precious time lost in the race against recovery from cancer.

By way of prophylaxis must be mentioned, early attention to all sources of chronic irritation as jagged teeth, poorly fitting plates or other dentures, persistent, thickened white patches of the mouth or tongue, and chronic indulant, slowly healing ulcer of the lip or skin. Beware of any ulcer or sore that has lasted over a month or two, the mole that suddenly increases in size, chronic "erosions of the cervix" of the uterus, "cystic cervicitis," "cervical" or "rectal" polyps, etc. All these need careful and immediate attention as possible causes of chronic irritation which if persisted in may lead to cancer. Pay strict attention to oral and bodily hygiene.

Where in the body does cancer occur and what are its early symptoms and signs? Cancer may occur in most any organ of the body but some more predominatingly than others. Thus cancer of the genital organs, especially the cervix and in the breast are most common in women and of the stomach, mouth and rectum in men.

Cancer commences as a small lump or tumor and is insidious in onset, generally free from symptoms in the beginning and only when easily within reach of the examining hand, or the sight of the eye or *x*-ray is the lump or tumor recognizable. It is at this stage that cancer should be diagnosed if we wish to secure best result. And here I might stress the value of periodic health examinations in attaining this end. Later in the course of the disease the tumor tends to spread by a process known as metastasis and some types spread very easily even to distant parts which again emphasizes the importance of early recognition and treatment. Such metastasis occurs by way of the lymphatic or blood stream and while microscopic at first becomes recognizable later as demonstrable nodules in the lymph-node or other organs. In this stage it is often too late to expect cure and nothing beyond palliation can usually be offered. Again the dreadful price of procrastination!

About this same time ulceration tends to occur producing mild bleeding or discharges. The aforementioned are classed as fairly early signs of the disease while pain is generally absent till late in the disease and should never be awaited before seeking medical advice.

How then can we be forearmed and forewarned? Only by "eternal vigilance" which is "the price of safety." After passing the age of forty be sure to go to visit your doctor at least once a year for a physical "check up." Women should especially be on the lookout for lumps in the breasts even though painless, retraction, deformities or discharges from the nipple, dimpling or puckering of the skin of the breast or lumps in the armpit. They should also beware of bloody or watery uterine discharges or irregular menstrual bleeding. Everyone should take heed of the passage of blood in the urine or from the bowels. Don't blame the latter onto supposed "piles" and pass it off as harmless without first seeking medical advice. Beware of slowly healing ulcers of the lip mouth, tongue or skin. Don't let such conditions exist over a month without consulting your physician. In cases of chronic indigestion and constipation accompanied by loss of weight, routine fluoroscopic or *x*-ray examinations of the gastro-intestinal tract are in order and can be arranged for through the clinic where necessary. The appearance of a lump anywhere in the body should arouse our suspicions and prompt us to immediate action before it is too late.

Some types of this disease are most amenable to treatment than others. Under present methods of treatment, cancer of the lip and skin have shown promising response; cancer of the cervix in women has lost much of its past dreadfulness, thanks to the advent of radium but still with the aid of radium, *x*-ray and surgery much remains to be done and people still have cancer and many die from the disease. Everybody is eager to see improvement, if possible in our present methods so as to obviate this dreadful mortality and you can rest assured the medical profession and the rest of the scientific world are not asleep on the job.

There are three essentials of merit in the treatment of cancer. They are early diagnosis, surgery and radiation. Biopsy, or the removal of small bits of tissue for microscopic examination is always to be advised where permissible. This should be followed by immediate provision for complete eradication of the localized disease either by the cold knife or the radio knife, if possible preceded and followed by *x*-ray or radium

packs, or the use of radium needles, tubes or seeds interstitially. Thus, in this triad of early diagnosis, surgery and radiation we have our present mainstays in the fight against this dreadful disease.

You will say that this is expensive treatment and none but the wealthy can afford it. Radium costs $70,000 a gram; approximately 1-30 of an ounce. Operations and hospital bills are costly too. This is just why the State of Massachusetts has been pioneering in this field by establishing clinics and making radium and *x*-ray available at Pondville when necessary. If we stop and look back at the tuberculosis problem of 30 years ago we will note that the outlook was equally discouraging. We have no positive cure for tuberculosis yet, in spite of that we organized campaigns against the "white plague" and sailed upon an unchartered sea, not knowing whither bound but with a decided intention to achieve something worth while. In due time state aid was extended to the working classes thus securing for them the necessary sanatoria rest; legislation was passed to improve general hygiene conditions and so in short tuberculosis to our great satisfaction has ceased to be as ravaging as it was. Who knows that with state and federal aid we may not be able to do as much for the cancer problem. At least, this is the way many states and countries of Europe are viewing the situation and let us hope the effort will be equally rewarded.

Lastly, but not least, don't be deluded by short or sure cure promises or advertisements, by radio talks from station KFKB; by the Koch treatment emanating from Detroit with satellite Judases all over the country eager to prey on cancer victims; by Abram disciples who claim to diagnose and treat cancer, syphilis and tuberculosis especially, by determining the vibration rates and using this vibration rate in treatment; by Glover's or similar sera, dietatetic or drug treatments. All so far, to the best medical knowledge have been tried and found wanting. Even the lately and much-heralded Coffey-Humber treatment seems to be rapidly proving a failure.

Let us therefore learn to be cancer minded but not absessed with cancer phobia. Let the family physician remember that much depends on him in this campaign against cancer but that he is powerless if the individual fails to give heed to early warnings and seeks him in consultation too late.

Your state health department has recognized the need and under the guidance of its Commissioner, Dr. Bigelow has been pioneering in this field. They have established an efficient series of cancer clinics with the aid of locally interested groups of physicians and town folk. The legislators have done their part by voting their financial support so now it is up to the people of the state to get the most possible benefit from the clinic. Let us all receive the warning and accept the challenge of the clinical opportunities afforded.

ANAESTHESIA IN GOITRE SURGERY — EXPERIENCE WITH AVERTIN

By ARTHUR S. McQUILLAN, M.D., NEW YORK, N. Y.

From the Goitre Clinic, Fourth Surgical Division, Bellevue Hospital.

THE choice of an anaesthetic is a factor that contributes not a little to the success of thyroid surgery especially when dealing with cases which have been thyreotoxic and when one is forced to do the least amount of surgery on a patient who is at the time thyreotoxic to a greater or lesser degree.

Ether has always been an unsatisfactory anaesthetic. For unknown reasons, it increases the hazard in these cases as it does in the diabetic. It is a vascular stimulant increasing the force and the rate of the heart and obviously undesirable in thyreotoxic patients.

Nitrous oxide-oxygen, or better, ethylene-oxygen, have come to be the anaesthetics of choice. The rapidity of induction, the light degree of anaesthesia, the excellent color of the patient throughout the procedure, and the quick return to consciousness characterize especially ethylene anaesthesia. While due regard to the explosive character of ethylene has to be taken, with proper precautions it can be used with safety. Its advantages in thyroid surgery outweigh the inconvenience and extra equipment for carrying out safety measures.

Local infiltration or block anaesthesia has been used extensively in the past, and is much used at present. In general it is satisfactory. Occasionally patients refuse it and in oversensitive, high strung thyreotoxic cases, one runs into difficulties. Also, one meets a patient who is hypersensitive to novocaine. The author has had several such cases with one fatality directly traceable to novocaine toxemia. On the other hand it has been the author's experience that post-operative thyroid reactions when they do occur are much less severe after the use of a local infiltration or block anaesthesia. Occasionally it is advantageous to supplement inhalation with local or infiltration anaesthesia. This carries out the principle of anoci-association formerly pointed out by Crile, who recognized the fact that reflex stimuli in-

creased the thyreotoxicosis even with the patient under the influence of inhalation anaesthesia. Reflex stimuli, as emotional shock, fright, fear, anxiety, worry, the mechanism of which is little understood, except that they are associated with loss of energy, present problems which are most intangible and difficult to solve Shock and fright may have a profound influence on the nervous mechanism even in the normal subject. These factors are frequent in the predisposing and contributing etiology of Graves' Disease. They constantly intensify and aggravate this glandular disturbance when it exists. They are often responsible for converting an excellent surgical risk into a poor one. Crile minimized effects of these disturbing factors in his method of gradually training the patient to become accustomed to the anaesthetic thus stealing the most opportune time so to speak for the surgical procedure. This method necessarily involves much time, patience and expense and has not been generally used in hospitals not especially equipped and constructed. Hence there has been a need of some simple, safe and effective method of meeting these difficulties, and for this reason I am reporting my experience with avertin used in a series of one hundred Exophthalmic Goitre cases.

Avertin (tribromethanol) was used in these cases with the sole object of initiating narcosis, the degree of unconsciousness necessary for the surgical procedure being accomplished by supplementary inhalation anaesthesia. Avertin exists in liquid form, being held in solution of amylene hydrate. Each cc of fluid equals a gram of avertin and this is given per kg of patients weight. The estimated quantity of the drug is added to distilled water heated to 40 degrees C and shaken to make a 2½ per cent to 3 per cent solution. The temperature must not go above 40 degrees C, otherwise, irritating hydrobromic acid will be formed. This latter is recognized by a blue color, when a few drops of congo-red (1-1,000 sol.) is added to 5 cc of this avertin solution.

The procedure is as follows: The patient is given a simple enema each morning for three or four days preceding the day set for operation, the patient being kept entirely ignorant of the latter. This enema is given fairly early in the morning before the usual time for breakfast. On the morning of the operation the estimated dose of avertin is introduced into the enema of distilled water and this is given in the usual way in patient's room and with patient on left side. Narcosis takes place within three to five minutes following the injection of the avertin enema. The patient is then taken to the operating room where inhalation anaesthesia (usually nitrous oxide oxygen or ethylene oxygen) is supplemented. It is found unnecessary to use the usual preliminary dose of morphine in these cases. The simplicity of this method and the ease, comfort, rapidity and certainty of the narcotic effects of this drug mark its value. In this group of cases the method and reason for using this drug have been aimed at the psychical strain and unpleasantness always inseparable from simple inhalation anaesthesia. No attempt has been made to use avertin as a basal anaesthetic in these cases. For this reason a dose of the drug merely necessary to produce a light stage of unconsciousness has been used. Hence a wide margin of safety has been maintained.

The results in this series have been excellent. There have been no accidents attributable to avertin. Only one case was moderately cyanotic during the operative procedure. This condition quickly cleared after the operative procedure. It was learned later that by error this patient was given a preliminary dose of morphine. As avertin in its larger doses may have a depressant action on the respiratory center, and in view of the morphine-like action of this drug, the use of morphine would seem unnecessary and contraindicated. There has been no noteworthy change in the blood pressure, in any of these cases while under the influence of avertin. The narcosis with this minimal dose has lasted on the average of one hour post-operative. The amount of inhalation anaesthetic necessary to carry the patient through the operative procedure has been reduced to at least one-third. The usual amount of post-operative nausea and vomiting has been greatly diminished. At times sagging of the jaw and blocking of the upper respiratory tract by the tongue have been noted. This must be constantly watched during the whole time the patient is under the influence of avertin and especially after the patient is returned to the bed.

I recommend that avertin be handled by only the best qualified anaesthetists. While under the influence of avertin, the patient must be watched as carefully as under any other anaesthetic. If this is followed I believe avertin a most useful and safe adjunct to inhalation anaesthesia in thyroid surgery.

Pub. Health and Med. Education—T. P. FARMER, M.D., Syracuse
Scientific Work—ARTHUR J. BEDELL, M.D.....Albany
Medical Economics—GEORGE F. CHANDLER, M.D.....Kingston
Public Relations—JAMES E. SADLIER, M.D.....Poughkeepsie
Medical Research—JOSHUA E. SWEET, M.D.....New York

CHAIRMEN, SPECIAL COMMITTEES

Group Insurance—JOHN A. CARD, M.D.....Poughkeepsie
Periodic Health Exam's—C. WARD CRAMPTON, M.D....New York
Nurse Problem—NATHAN B. VAN ETTEN, M.D.....Bronx
Physical Therapy—RICHARD KOVACS, M.D.....New York
Anti-Diphtheria—NATHAN B. VAN ETTEN, M.D.....Bronx
Prize Essays—THOMAS H. CURTIN, M.D.....Bronx

PRESIDENTS, DISTRICT BRANCHES

First District—GEORGE B. STANWIX, M.D.....Yonkers
Second District—CHARLES H. GOODRICH, M.D.....Brooklyn
Third District—EDGAR A. VANDER VEER, M.D.....Albany
Fourth District—WILLIAM L. MUNSON, M.D.....Granville
Fifth District—AUGUSTUS B. SANTRY, M.D.....Little Falls
Sixth District—GEORGE M. CADY, M.D.....Nichols
Seventh District—E. CARLTON FOSTER, M.D.....Penn Yan
Eighth District—W. ROSS THOMSON.....Warsaw

SECTION OFFICERS

Medicine—JOHN WYCKOFF, M.D., *Chairman*, New York; DAVID A. HALLER, M.D., *Secretary*, Rochester.
Surgery—CHARLES W. WEBB, M.D., *Chairman*, Clifton Springs; ARTHUR M. WRIGHT, M.D., *Secretary*, New York.
Obstetrics and Gynecology—ONSLOW A. GORDON, JR., M.D., *Chairman*, Brooklyn; GEORGE H. BONNEFOND, M.D., *Secretary*, Utica.
Pediatrics—MARSHALL C. PEASE, M.D., *Chairman*, New York; DOUGLAS P. ARNOLD, M.D., *Vice-Chairman*, Buffalo; BREWSTER C. DOUST, M.D., *Secretary*, Syracuse.
Eye, Ear, Nose and Throat—CONRAD BERENS, M.D., *Chairman*, New York; RICHARD T. ATKINS, M.D., *Secretary*, New York.
Public Health, Hygiene and Sanitation—ARTHUR T. DAVIS, M.D., *Chairman*, Riverhead; FRANK W. LAIDLAW, M.D., *Secretary*, Middletown.
Neurology and Psychiatry—NOBLE R. CHAMBERS, M.D., *Chairman*, Syracuse; IRVING J. SANDS, M.D., *Secretary*, Brooklyn.
Dermatology and Syphilology—EARL D. OSBORNE, M.D., *Chairman*, Buffalo; LEO SPIEGEL, M.D., *Secretary*, New York.

LEGAL

Office at 15 Park Place, New York. Telephone, BArclay 7-5550

Counsel—LORENZ J. BROSNAN, Esq. *Attorney*—THOMAS H. CLEARWATER, Esq.

Executive Officer—JOSEPH S. LAWRENCE, M.D., 100 State St., Albany. Telephone, Main 4-4214.

For list of officers of County Medical Societies, see this issue, advertising page 777ii.

Next Annual Meeting, Hotel Syracuse, Syracuse, N. Y., June 1, 2, 3, 1931.

CHANGE OF ADMINISTRATION

This is the last Journal to be issued before the change of officers which will occur at the annual meeting beginning on June 1st. Yet the change in personnel will not be great, for when a member is initiated in his official duties, he remains in active service for years. Every surviving past president of the last decade for example is still on the active list as a member of some committee or unit of administration. The Medical Society of the State of New York is fortunate it has a body of experienced men on whom it can rely for advice and leadership.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 23

This article closes the President's Comments of the year.

The year's work is characterized by an orientation of the situation in medicine not anticipated in the beginning. That some suggestions of the President should be considered innovations is not surprising. That they should arouse psychological factors involved in any readjustment of attitudes toward the problems of medicine is not unusual. So prolonged a study of medical relationships and the problems of medicine in as extensive a field as has been done in New York State this year could hardly fail to reveal the true situation in medical relationships and problems. While all the suggestions of the year are minor ones in comparison with those called the "innovations of medicine," it is quite likely that they have met with similar reception.

To discuss social evolution and the medical problems arising from it seems to suggest socialism to a considerable number of physicians, but I am bold enough to say that this attitude will not save us from the influence of certain inevitable changes in our national life already begun and advancing. America is steadily approaching the settled state of the older nations. The trend of national opinion is reflected from time to time in the enactment of laws. We have various kinds of registrations and restrictions and taxations and other evidences of the government taking on more and more its parental functions.

All these things are simply the penalties of the onward progress of civilization and the limitation of independent action. These conditions are not the result of the advocacy of any group or of any individual. They depend upon certain incontrovertible facts.

No one can for long raise false issues. Whatever the facts are will determine the issues. Let anyone study the social conditions in this country; take into account those of older countries; realize that we have passed the period of most rapid growth as a nation; and that there is a steadily increasing reciprocal influence on this country of conditions in other countries. Though someone will rise up to object, I doubt not the influence on this country of the five-year plan and multiples of it in Russia if it succeeds. Its present duration has already had an influence. Let anyone study the new book, "Business Adrift," by Donham, Dean of the Business School of Harvard, substituting "medicine" for "business" and see where he stands when he has finished.

About at this point some reader will say, "What has all this to do with medicine?' Let us see if it has any relationship. Medicine has always been a social function. It has always been intimately related to human welfare and human progress. Fear of pain and death are universal human characteristics. Any force great enough to postpone either of these fears is to intimately associated with all the social influences surrounding individual or community or national life that it cannot escape being influenced by them.

The next step in our reasoning is the logical one that the science of medicine has had a phenomenal advance. Almost nothing has gone faster in human affairs than the accomplishments of medical research, and the development of methods to cure and prevent disease. There has come to be definite public understanding of the resources of medicine. This conception is likely to increase just as education advances and general ease of communication increases, and as facilities for the spread of knowledge become more available.

The next step is that the public wants these services. Official organization, voluntary organization, and government are representing the public in its desire. The National Committee on the Costs of Medical Care, the White House Conference on Child Health, the American Federation of Organizations for the Hard of Hearing, the National Committee for the Control of Cancer are examples of only a few of the organizations to advance plans for placing the resources of medicine within public reach. Some of the greatest minds in medicine today are associated with these efforts. Some of them are leaders in organized medicine. Their loyalty to the interests of the general practitioners of medicine has never been questioned.

The next logical step in our reasoning is that people get sick as they used to do. Babies are born as they always have been. There is more work to do in curative and in preventive medicine together than there ever has been in curative work alone. Aside from whether there may too many doctors or not, there is no question that there is an economic disturbance in the practice of medicine. This disturbance is not because somebody else is practicing medicine, but because there is not money enough in the pockets of all the people to pay for modern medical care in sickness. No deluge of words will obscure this fact.

Let us bring in right here another fact because it belongs here. Modern medical knowledge for the prevention of disease and modern public health practice are not as available as they should be in New York State. The greater the availability of modern means for the prevention of disease, the greater the need for physi-

to apply them. The more foundations er in medical research regarding the inci- of disease and stimulate early diagnosis, nore work there is for physicians. The defect in this chain of reasoning is that e must be some method of providing ns to meet the costs of medical care for ɔe who cannot get it themselves. Medicine uld be the leader in developing any plan do this, not because it is more able in an uarial sense—some expert would have to this—but because this involves problems of eat importance in relationships. As a con- ibution to the situation in medicine, anyone terested might read with profit an article by r. Winford H. Smith, Director of the Johns Iopkins Hospital, on Page 10 of the May 16, 1931, issue of the *Saturday Evening Post*.

If the availability of modern medical care is not as great as it should be; if public health practice is not as well organized as it should be; if a considerable part of the people cannot without hardship pay for modern medical resources; and if there is an economic disturbance in the general practice of medicine, then it is time to begin to think clearly of medical problems and relationships. The general practitioner, the most useful man in all medical relationships, has great competition today. Hospitals, clinics, group practice, and specialism are major examples. Will it suffice to oppose changes in medical service when these changes are inextricably involved in the social complexities of modern national life and the national inter-relationship of health problems?

My studies this year plainly indicate to me that there are "rocks ahead." The approach is not rapid enough to alarm anyone not paying special attention. The fact that leaders in medicine in many places are considering the situations in medicine should be sufficient reason for the profession to consider the facts impartially.

What is the objection? What are the psychological factors? Is it fear of something unknown to come? Is it because that any innovation or change has always met resistance at first? Recall the Holmes' and Semmelweis' opposition led by the obstetricians of Philadelphia; the opposition to vaccination a hundred-thirty years ago in Boston, and the opinion of Benjamin Waterhouse held by the Medical Society of Massachusetts. Recall the influence of the test instituted by the Boston Board of Health about the year 1802; the opposition to dissection; to Harvey's theory of circulation; to the discoveries of Pasteur; to the doctrine of antiseptics; to asepsis; and then to other things that everyone can recall.

Perhaps destructive criticism is the natural attitude instead of constructive criticism, just as war and not peace, is the natural state of all nature.

Now let us look at the psychology involved. For this I am partly indebted to "Social Factors in Medical Progress" by Stern.

It is quite usual that any proposal involving a change from the customary way of doing things, even though the results are inefficient, is not approved until a considerable time has elapsed. The second factor is the "power of tradition." Space will not permit its discussion. The third factor is conservatism. The physician is naturally cautious because he deals with a multiplicity of uncertain factors and it forms a background for resistance to change in medical relationship involving new things in the practice of medicine or the practice of public health. Another factor is emotional resistance to a substitution of a new proposal for an existing one. Another factor, as much sociological as psychological, influencing the acceptance or rejection of an innovation, is vested interest. In a restricted sense this means economic interest; in a larger sense it means any disturbance of reputation, prestige, or authority.

Just to recognize that there is a problem in medicine is important. Until the profession sees that there is a problem, there can be no solution. Medicine should have a sufficiently definite and formulated policy or plan to guide it in its attitude toward readjustment of relationships to present day conditions in regard to the major problems of health and sickness service and in the promotion of the health and welfare of the community. Organized medicine in New York State has made a definite advance this year. At least a major part of the profession recognizes the situation in medicine. In no way does this involve the science of medicine. Its phenomenal progress will doubtless continue. A measurement of medicine's relation to public health is reflected in the enactment of eight new health laws. Notwithstanding this, the leadership of medicine in all health activities can be improved. This would be both in the interest of the profession and in the interest of the public. Increased cooperation with all health influences under the technical leadership of medicine will go far toward the correction of the economic disturbance of the general practitioner.

There are many things which I wanted to discuss in this issue of the Journal, but space is too limited to do so. I would like to call attention to the outstanding work of some of the committees in their efforts to evaluate the services that they render. This is the most outstanding observation of the last few weeks.

I have written for every issue of the Journal this year. The object has been publicity of

the activities of the administration I do not intend it to be a challenge for the fut...

In closing the year's work I can ...ukly of the coop...ion of ... and the pl...ure that it has given me. I trust that there has been some contribution to the solution of the problems of medicine. I regret that this article is my valedictory.

WILLIAM H. ROSS.

PRESIDENTIAL OPPORTUNITIES

Progress of the Medical Society of the State of New York during the past year has been the most marked along the lines of adjusting medical service to the needs of the people. The medical profession has expanded its field of activities beyond the relief of individual cases of actual sickness and disability, and has included disease prevention in its program. It has also advised and inspired the people through their organizations, both official and civic, to assume the economic burden of the cost of sickness among those who are unable to bear it.

The practice of medicine was formerly confined to relief given by individual doctors to individual patients. The past year has seen the general acceptance of the principle that physicians in regional groups or medical societies shall give medical advice to municipalities as their patients. The representatives of the State Medical Society have given medical advice to officials in various branches of the State Government—departments of Education, Labor, Health and Public Welfare—and induced them to extend the aid of the State along public health lines. The same principle has been applied by county medical societies in dealing with county officials, and by smaller groups of doctors dealing with villages and school districts.

These principles, proclaimed by the President of the Medical Society of the State of New York throughout the past year, have been generally accepted by physicians, by governmental officials, and by the people. The President has given his time and energy without reserve to the great work of inspiring both the medical profession and the municipalities to join in the great task of making all forms of medical service available to all classes of people. He has devoted almost his entire time to the duties of his office, and has demonstrated the great need of unselfish medical leadership, such as that which he has given. It may be that in the future a portion of the work in which the President has been almost a pioneer will be allotted to his associated officers—the President-elect and the Vice-Presidents. The new officers will have the advantage of the self-sacrificing example of President William H. Ross.

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

News Items: Physicians today will be interested in the following news items contained in this Journal of June, 1906:

"Tribute to Dr. Austin Flint:—On the occasion of the retirement of Dr. Flint as professor of physiology at Cornell University Medical School, the Class of 1909 presented him with a loving cup appropriately inscribed.

"Dr. Albert VanderVeer, of Albany, who was recently elected a member of the State Board of Regents of New York, took the oath of office on May 10th.

"Opening of Rockefeller Institute:—On May 11, this institution, which was founded in 1901 by John D. Rockefeller, had its formal opening ceremonies. Addresses were made by President Eliot of Harvard University, President Butler of Columbia University, and the President and Secretary of the institute, Dr. William H. Welch and Dr. L. Emmett Holt. At present there are twelve experimenters at work under the supervision of Dr. Simon Flexner. When entirely completed there will be accommodation for 50 workers. Investigation will be carried on in experimental pathology, bacteriology, physiology, physiological and pathological chemistry. The only other institute of its kind is in Germany. Reports on experimental work are published in the *Journal of Experimental Medicine,* which is issued by the Institute bi-monthly.

"Dr. Arthur Woodward Booth, of Elmira, has been duly appointed Examiner in Surgery in the State Board of Medical Examiners to fill the vacancy in that topic caused by the death of Dr. George Ryerson Fowler, to serve until the next annual meeting of the Board."

MEDICAL PROGRESS

Glaucoma.—William D. Rowland believes ere are many neglected cases of glaucoma of ie non-inflammatory type, in which the non-dical refractionist changes the patient's glasses veral times without recognizing the condition. ne general practitioner will detect some cases, ut not all. Great care must be exercised in the interpretation of the patient's complaint, and it is important that the public be educated to the greater service that a medical refractionist can give. The diagnosis of glaucoma is made upon one finding, namely, increased intraocular pressure, determined by palpation of the eye by trained fingers, or more accurately determined by a tonometer. There are two types of glaucoma: the acute inflammatory type, which is always painful, in which there is sudden loss of vision, and for which the patient seeks medical aid immediately; and the non-inflammatory type, in which there is no pain, the eye is white, and a slow irrecoverable loss of vision ensues. A rule to follow is the careful investigation of every case of loss of vision, particularly the sudden losses. Frequent desire for change of glasses or marked changes in vision should lead one to be suspicious immediately of glaucoma, possibly of diabetes, intraocular disease, or intracranial complications. In the large majority of glaucoma cases medical measures should be tried first and, if the intraocular tension is not quickly brought down, an operative procedure is necessary in order to stop further loss of vision by pressure on the retina and optic nerve. The medical treatment consists in the use of miotics—pilocarpine 1 per cent or eserine 0.5 per cent—instilled from once every two hours to two or three times a day. Morphine is particularly well suited to the painful type because it produces a small pupil and helps to quiet the patient. Local application of heat to the eye, the patient being kept quiet with the head raised, usually aids in the vascular outflow. Good elimination from the intestinal tract is advisable. If the acute attack is not under control within twenty-four to forty-eight hours, an operation is indicated, usually a wide iridectomy. The non-inflammatory type requires only miotics, but it is not considered safe to continue with these unless the tension is quite promptly brought to normal. —*New England Journal of Medicine,* March 26, 1931, cciv, 12.

Zona Ophthalmica and Glaucoma.—On the basis of an illustrative case, A. Colrat shows that acute glaucoma may be a complication of zona ophthalmica. The prognosis as regards vision is generally grave, and iridectomy is usually necessary. It is generally an acute, unilateral glaucoma on the side of the herpetic eruption. The early pain attending the eruption has left or diminished, but returns with redoubled intensity. There are dilatation of the pupil, pericorneal injection, and hypertension. In the author's case, there were two stages: first herpetic pain radiating into the hemicranium, then 2 weeks later, pains of glaucoma type, periorbitally localized. In some cases, however, glaucoma has been known to precede the eruption by a few days. Diagnosis is usually easy, provided its possibility is borne in mind and a systematic examination is made of the ocular tonus of every patient suffering with zona ophthalmica. The evolution of the glaucoma is very various in individual cases. One should bear in mind that the nutrition of the eyeball is disturbed in zona ophthalmica, and that infectious complications are to be feared. Iridectomy should be postponed until the upper eyelid is disinfected and cicatrization of the zona vesicles is complete. As regards pathogenesis, the attack of glaucoma, even without zona, suggests a sympathetic trouble, viz., abrupt hypersecretion of aqueous humor, with acute vasodilatation. The participation of the sympathetic in the herpetic process is easy to conceive, for the inflammation may reach the sympathico-gasserian anastomosis and the long ciliary nerves. The effect of the sympathetic upon ocular tension is not well understood, but in a general way it may be recognized that in zona ophthalmica there are signs of sympathetic deficit, while glaucoma seems to be related rather to sympathetic excitation. However, it appears that ocular tonus is not regulated solely by the sympathetic, and it is possible that the action of the herpetic virus may be exerted on other nerve fibers. The problem is complex. The facts are that zona ophthalmica may accompany troubles of ocular tension in either direction. It cannot be too often repeated that a patient with zona ophthalmica is liable to lose the sight of an eye, for multiple reasons, one of which is glaucoma. The possibility of glaucoma should be recognized, in order that effective therapy may be instituted in time.—*Journal de médecine de Lyon, March* 20, 1931.

The Mean Blood Pressure in Glaucoma.—Baillat and D. M. Gomez say that as the result of preliminary studies it appears that the mean blood pressure is of great importance in glaucoma, since it is possible by this means to recognize arterial hypertension that would otherwise go unnoticed. For some time they have been determining this mean pressure in all their cases

of glaucoma, and have almost invariably found it increased, sometimes in very great degree. In some of the subjects the systolic and diastolic pressure would have passed for normal while the mean pressure showed a definite increase In 10 of 17 subjects examined the systolic and mean pressures were both increased, but the latter always proportionately to the former. In 6. however, the only abnormal increase was in the mean pressure. In one case in a man of 28 with no symptoms other than ocular a systolic pressure of 155 mm. Hg. was found and, to the authors' astonishment, a mean pressure of 135 mm. In this patient the heart and aorta were found greatly dilated in the roentgenogram. In a boy of 14 with chronic glaucoma, regarded as of normal tension, the mean pressure was found to be 110 mm. Hg. instead of 80-90 mm., which is usual at that age. Heart and aorta were of normal size radiographically, but the latter was of exaggerated opacity, indicating an advanced sclerosis in one so young. One is thus forced to regard ocular hypertension as the direct and immediate result of arterial hypertension. There can be no doubt that the increase of mean pressure in glaucoma is due to lesions of the small arteries and capillaries, and to troubles of exchange resulting from these. A number of ophthalmologists have insisted upon lesions of the vascular system in this affection. If these lesions involve the small vessels they may also be present in the large arteries. The authors were impressed by the observation in 2 patients, who were still young, of an abnormally exaggerated lesion of the aorta, visible in the entire posterior mediastinum upon roentgenologic examination, and an enlargement of this same vessel in a glaucoma patient of 28. It appears that the attention of physicians should be drawn more and more to the vessels in cases of glaucoma, and that the study of the mean pressure may furnish valuable information with regard to the true state of the arterial pressure. The fact that this increase of mean pressure exists not only in adults and aged persons but also in juvenile forms is of great significance.—*Bulletin de l'Académie de Médecine,* March 24, 1931.

Trigeminal Neuralgia and Its Treatment.—Wilfred Harris, writing in *The Lancet,* March 14, 1931, ccxx, 5611, enumerates the many exciting causes that may start trigeminal neuralgia, such as cold wind, violent emotion, a blow in the jaw or face, a severe dental extraction, etc. It is especially the middle and lower divisions of the fifth nerve that are liable to severe neuralgia, and this gives a clue to the original causation of the disease. These two nerves supplying the buccal cavity are subject in the majority of people to constantly recurring sepsis in their terminal branches in the gums, teeth, and tonsils, to a degree that no other nerves in the body are exposed. It can scarcely be doubted that this is the primary cause of their becoming foci of neuralgic spasms. When the pain is comparatively slight and does not interfere with the normal life and work of the patient no more drastic treatment may be required than radiant heat, ionization, and perhaps gelsemium and the milder analgesics. Morphine, heroine, and cocaine must be avoided entirely because of the danger of drug habituation. When the milder methods fail to afford relief, either the open gasserian operation for resection of the sensory root within the cranium must be undertaken by a skilled surgeon, or else alcohol injection of the offending nerve trunk must be performed at either the foramen ovale or foramen rotundum. When both upper and lower jaws are involved in the neuralgia, injection of the ganglion is preferable. During the last twenty-three years Harris has treated over 1100 cases of trigeminal neuralgia, and with increasing experience he is convinced that the nerve should be injected at the foramen ovale or rotundum. This relieves the pain for at least a year, and often for much longer. Cases in which the neuralgia has returned after injection of a nerve trunk are often more difficult to inject than a fresh case. For this reason it is advisable to inject the ganglion if the neuralgia returns within eighteen months of the first injection. Morphine-hyoscine anesthesia is preferable to chloroform or ether inhalation narcosis. Usually ¼ grain of morphine and 1/150 grain of hyoscine suffices. Often the operation can be performed with the use of local novocaine only.

Studies of Relatively Normal Obese Individuals During and After Dietary Restrictions.—In an investigation of 7,530 Home Office employees of the Metropolitan Life Insurance Company in 1921, H. H. Fellows states that 558 (7.4 per cent) were 20 per cent overweight, and 121 (1.6 per cent) were 40 per cent or more above average weight. Approximately the same incidence of overweight was found among the policyholders of the company. Starting in 1923, 294 of the overweight employees undertook treatment for obesity. Of these all but 33 could be classed as normal healthy adults. The parents of the overweight subjects showed an incidence of overweight in 24 per cent of the cases, thus tending to substantiate the statement that heredity plays a definite part in the production of some types of obesity. Overweight in the group studied occurred in both males and females before the age of 30 years. The treatment consisted almost entirely in the strict adherence to a reduction diet combined with carefully directed exercises. About 75 per cent of the 294 who undertook treatment established a definite weight loss while under observation. At the end of one year 32 per cent had continued to lose weight, and 68 per cent had regained some of the weight lost. Five years after completion of treatment, 193 of

the group were examined; 21 per cent had continued to lose weight, while 79 per cent had regained in whole or in part the weight lost during treatment. It is a relatively easy matter to reduce overweight, but much more difficult to maintain weight at a reduced level. Of the 294 employees only 33 showed physical signs of disease before commencing treatment, and these showed less evidence of physical abnormality five years after completion than at the beginning. Patients suffering from hypertension with or without cardiac complication may be benefited for years simply by reduction of their overweight, and especially where weight at a lower level is maintained. There was no consistent trend evidenced either in repeated basal metabolic rates or respiratory quotients, before, during, or after weight reduction. The results obtained by the administration of thyroid were not brilliant and its use was discontinued.—*American Journal of the Medical Sciences,* March, 1931, clxxxi, 3.

Spontaneous Rupture of the Spleen in Inoculation Malaria.—Bernhard Jutz and August Jacobi, writing in the *Münchener medizinische Wochenschrift* of March 6, 1931, point out the extreme rarity of spontaneous rupture of the spleen, and its even greater rarity in inoculation malaria, only two other cases having been found in the literature, although this treatment of progressive paralysis has been generally accepted as the sovereign method. Enlargement of the spleen, as Gerstmann and others have shown, is commonly lacking in artificial malaria. To the two cases already reported the authors add a third. The patient, a man of 39, suffering with tabetic paralysis, was reacting to the malarial treatment with the usual fever curve (40° C.—104° F.—at each chill) and with no untoward symptoms until, on the occasion of the seventh chill, the pulse suddenly grew rapid and weak. Digitalis was administered with no response, and the patient went into collapse and died within a few minutes. His extreme pallor suggested internal hemorrhage, and at autopsy 2,000 c.c. of blood was found in the peritoneal cavity which had come from a rupture 5 cm. long and 1 cm. wide in the enormously swollen spleen. Microscopic examination excluded any chronic pathologic changes of the spleen predisposing to rupture. There was, on the other hand, an acute infectious hyperplasia corresponding to the anatomic finding of a soft, pulpy spleen in which the plethora (on account solely of the rupture) was relatively small in comparison with an enormous polymorphocellular hyperplasia of the pulp. The question whether with such a high grade enlargement of the spleen a genuinely spontaneous rupture can occur without any external causation is here answered with great reserve. As a rule insignificant acts, such as sitting up, coughing, vomiting, etc., serve as the exciting occasion of the rupture. In this case violence from outside could be certainly excluded, but the possibility of one of the above causes cannot be entirely denied. Whether under such circumstances a rupture should be called spontaneous must be left to the individual medical attendant to decide. The malaria must be admitted as the cause of the spleen's enlargement. An acute congestion as the result of sudden cardiac insufficiency seems to be excluded by the pathologico-anatomical findings.

Bath Treatment for Deafness.—James Adam, writing in the *British Medical Journal,* April 11, 1931, i, 3666, reports several illustrative cases of chronic progressive deafness in which definite improvement was obtained by a course of baths. He recommends immersion for ten to fifteen minutes, at bedtime, in a hot bath to which one pound of Epsom salts has been added. The bath is repeated every second night for a week or longer according to the indications. As the hearing improves the baths are given at longer intervals. In the less chronic cases the response is seen more regularly. One patient who was suffering from Ménière's complex was greatly benefited by the treatment. While the method is likely to succeed only in a minority of chronic cases, it has given good results in patients in whom the usual methods had proved an utter failure. The baths are ineffective if they do not sweat the patient. In order to produce sweating it may be necessary to double the amount of salt. Treatment by the emunctories is an old established method, but far too little attention has been paid to the skin, and to the effects of sweating on the mucous membranes. As hot baths are exhausting, caution in their use must be exercised in elderly, weakly, and cardiac patients.

The Lesions of Latent Syphilis.—Aldred Scott Warthin states that the term active latent syphilis refers wholly to an infection not clinically evident, but which on microscopic examination shows perivascular infiltrations and proliferations. Such lesions are found usually in the aorta, myocardium, meninges, brain, liver, pancreas, adrenals, and testes. Nearly 100 per cent of cases of latent syphilis show focal lesions in the meninges. In the brain of the latent syphilitic, there will often be found on careful search small localized perivascular infiltrations, similar to those found in the brains of cases of paresis and cerebral syphilis. The hearts and aortas of practically all male latent syphilitics show latent lesions. Spirochetes are found in varying numbers in the myocardial lesions. In general it may be stated that a cardiac death is the most frequent form of death for the latent male syphilitic, and a very large proportion of the deaths in middle life from so-called "myocardial degeneration" are in reality the result of latent syphilis. In the modern treatment of syphilis there are no

secondary symptoms. A period of ten to twenty-five years may elapse before symptoms of latent infection again become manifest. In some cases the disease may never become active, but should such a patient die at any time an autopsy and thorough microscopic study will reveal the presence of small latent lesions. In other words, the modern treatment of the disease, like the old, results only in a clinical cure; in no case has the author seen an absolutely inactive instance of syphilitic infection. In a series of autopsies in the University Hospital at Ann Arbor, the incidence of latent syphilis, as diagnosed on the microscopical criteria, was for the decade 1910 to 1920, 43.7 per cent; for the decade 1920 to 1930 the average incidence was 25.7 per cent. In 1,675 autopsies lesions of latent syphilis were found in 408 males and 86 females. From a branch laboratory in Honolulu, out of 140 cases examined of persons dying over 25 years of age, active lesions were found in 70 or 48.6 per cent. The actual incidence of syphilis cannot be known until autopsies are made on every one dying and a thorough microscopic study shall have been made in every autopsy case. A negative Wassermann has little value in excluding the presence of latent syphilis; the Kahn test has shown a greater degree of accuracy.—*Southern Medical Journal*, April, 1931, xxiv, 4.

Rheumatic Peritonitis.—Francis C. Wood and E. L. Elaison present a case report and review of the literature which deal with the question as to whether rheumatic invasion of the peritoneum does occur. The patient, a girl aged 13 years, with a past rheumatic history and a well-marked rheumatic cardiac lesion developed lower abdominal pain, diarrhea, and signs of peritoneal irritation. Operation for what was supposed to be a ruptured appendix disclosed an abundance of clear fluid in the peritoneal cavity and an acute peritonitis of unknown etiology. No suppurative focus was found in the abdomen. Within a few days after operation the abdominal signs and symptoms largely subsided, but the fever and general phenomena continued unabated. Nine days after operation acute pericarditis developed, and after a stormy course of typical cardiac rheumatism of six weeks' duration the patient died. Cultures from the peritoneum and cardiac effusion were sterile. The literature contains a considerable number of cases of presumably "rheumatic peritonitis." In a certain number of these the presence of a peritoneal lesion was established beyond question. There is a striking clinical similarity among many of the reported cases. There is no proof that these peritoneal lesions are rheumatic in etiology, but the close clinical association of the peritonitis and the rheumatic fever suggests a common etiology. The peritoneal lesions do not resemble in appearance or in clinical course any other known type of peritonitis. The lesions found at operation have been inadequate to explain the abdominal signs and symptoms and the severe general reaction. In one fatal case of acute rheumatic fever a serofibrinous peritonitis was found, which resembled grossly and histologically coexistent, typically rheumatic lesions in the pleura and pericardium. It seems worth while, therefore, to bear in mind the possibility of rheumatic peritonitis in the differential diagnosis of abdominal pain when it occurs in a patient with signs of present or past rheumatic fever.—*American Journal of the Medical Sciences*, April, 1931, clxxxi, 4.

The Relation of Endemic Goiter to Topography of the Region.—It is a well-known fact, says J. Axel Höjer, writing in the *Schweizerische medizinische Wochenschrift* of March 21, 1931, that villages lying near one another not infrequently show a different frequency of goiter incidence. Reporting the results of a survey that he conducted in 1929 in 180 localities scattered throughout Sweden, this author states that the thyroid gland was carefully examined in every inhabitant in these villages, in order to estimate the relative strength of the goiter agent. Two topographical factors were found to be of special significance: (1) the proximity of water courses and (2) the nearness of a declivity of a certain kind lying above the place. High plains and low levels are found free from goiter, as are also the slopes of cone-shaped mountain peaks close to the peak. Broad watersheds are free from goiter near the ridge. Goiter is sure to appear if the declivity above a village is the even slope of a hillside, unbroken by valleys or ridges. If there is an abrupt descent of 1:10, or if the place lies 500 meters below the ridge, there will be goiter. If the place lies at the foot of a slope of the appropriate kind, there will be endemic goiter of a grade depending on the distance from the hill. If it is at the bottom of a depression influenced by a hill on both sides, the degree of goiter increases. Water courses with a flowing movement in a certain given direction offer an encouragement to goiter, as when they come from an overhanging slope. Even without a slope, large or swift streams in the immediate neighborhood may produce goiter. This is seen between branches of rivers or between a river and the sea, on peninsulas or near river bends. Again, when a narrow point of flat land in the vicinity of a river is wedged in between mountains and surrounded on all sides but one by long, low hills insufficient of themselves to cause goiter, the disease will be prevalent. If these are slopes abounding in water from which streams and cold evening air sweep down through the point of flat land, this will easily be the site of endemic goiter. Determinations to be valid must be made on a permanent population born and brought up in the region where the survey is made.

LEGAL

DOCTOR'S STATEMENT SUBMITTED BY INSURANCE BENEFICIARY NOT PRIVILEGED

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

We have previously commented in these columns on the rule which generally obtains in respect to the privilege which a patient is given by law against disclosure by a doctor of confidential communications between the patient and the physician, and on certain phases of the law by which such privilege may be waived and the testimony received in a judicial proceeding. The statute which is fundamental in matters of this sort is Section 352 of the Civil Practice Act, which reads as follows:

"Physicians and nurses not to disclose professional information. A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity; unless, where the patient is a child under the age of sixteen, the information so acquired indicates that the patient has been the victim or subject of a crime, in which case the physician or nurses may be required to testify fully in relation thereto upon any examination, trial or other proceeding in which the commission of such crime is a subject of inquiry."

In a recent case, a very interesting situation arose as to certain evidence claimed to be inadmissible on the ground of professional privilege. An action was brought against a life insurance company by the beneficiary of a life policy. The company had refused payment claiming that one of the conditions of the policy had been breached, namely, that the insured had been treated, within two years prior to the date of the policy, for a serious disease. The facts involved in the case were well stated by the court as follows:

"March 3, 1926, plaintiff caused the life of her son, aged fifteen years, to be insured by defendant. The application is not made part of the policy nor was any medical examination had. The policy, by its terms, is not to take effect unless, at the time of its issue, the insured is in sound health; and it is declared to be void, if, within two years prior to its date, he has been attended by a physician for any serious disease, complaint or operation, or if, before such date, he has had any disease of the heart. It also provides: '*Proof of claim.* In case of death of the insured, proofs of claim shall be made on blanks to be provided by the Company and shall contain full answers of the claimant, physician and other persons to all the questions asked therein and shall conform to all the requirements thereof.' On June 3, 1926, exactly three months after the date of the policy, the insured died, and plaintiff filed with defendant proofs of death prepared on forms provided by defendant. These documents in part consist of an undertaker's certificate and the claimant's certificate in which she states that the insured first complained of illness four weeks before his death, that such illness consisted of swelling of the feet, that the cause of death was hydrops and that the duration was only four weeks. She delivered another document to defendant as part of the proofs of claim. It is the attending physician's certificate prepared upon defendant's form. She introduced in evidence the undertaker's certificate and her own, but she marked only for identification that of the attending physician. Upon her objection the court refused to admit it. The error assigned in this judgment is the rejection of this document. If competent evidence, it would raise the most serious issues of fact whether at the time of the writing of the policy, the insured was in sound health, whether, within two years prior to its date, he had been attended by a physician for a serious disease and whether, before such date, he had any disease of the heart. In his certificate, the physician states that his first visit or prescription in the last illness of the insured was January 3, 1926, two months before the date of the policy and five months before the death of the insured, that health had been impaired two years before death, that he had attended the insured during the year 1924 for grippe and weak heart, that the cause of death was oedema, with '*insufficientia valv. mitr. et aortae*' as a contributory cause and that such condition had existed for two years. Attached to the certificate is a statement signed by plaintiff as claimant agreeing that the certificate shall be considered a part of the proofs of death under the policy in accordance with its conditions. After this document had been rejected, testimony was admitted to the effect that it had been read to plaintiff prior to the trial and that she had conceded its correctness. Plaintiff seeks to support this judgment upon the theory that the certificate was hearsay,

that her act in supplying defendant with it was involuntary and, therefore, does not constitute an admission by her of the facts therein stated and that it is privileged."

The highest court of our State decided that the physician's certificate was admissible, regardless of the claim of privilege, by reason of the fact that the physician's certificate had been voluntarily submitted as proof of loss, and was therefore a voluntary admission by the claimant that the statements contained in such certificate were true. The court argued that by voluntarily furnishing the company with said papers, she had made the physician her agent with respect to reporting dates, duration and nature of previous illnesses of the assured. The court stated in part as follows:

"She may not be held to a personal knowledge of the cause of death as described in abbreviated medical Latin, but she must be assumed to understand the statement that the insured had been attended for two weeks in the year 1924 for grippe and weak heart, an illness which is described by the physician in plainly written English, and the statement that the first visit or prescription during the last illness was in January, 1926, as well as the statement that health had been impaired two years prior to death. These expressions of fact she made her own. Indeed there is testimony which, if credited, proves that she conceded the contents of the certificate to be correct. * * * This paper unexplained by her and admitted by her to be part of the proofs of death is as much hers as if she had orally related their contents as facts. Its production by her is, *prima facie*, admission that the facts therein recited are true."

This ruling is in accord with an earlier dictum expressed by our highest court in a similar case which was in part as follows:

"The common law did not protect a physician from disclosing as a witness information acquired professionally from patients. The statute was intended to afford this protection and to protect the patient also. * * * The statute should have a broad and liberal construction to carry out its policy. By reasonable construction it excludes a physician from giving testimony in a judicial proceeding in any form, whether by affidavit or oral examination, involving a disclosure of confidential information acquired in attending a patient, unless the seal of secrecy is removed by the patient himself. The verified certificate of the physician which accompanied the proofs of loss was not competent original evidence of the cause of the death of the insured, nor was it offered as testimony of the physician as to that fact. The fact that the insured died of delirium tremens was material to the defense. The admission of a party in interest is as a general rule competent evidence against him. The presentation of the physician's certificate that the deceased died from the cause stated, operated as an admission by the guardian that the fact was as stated. It derived its force from the fact that the claimant communicated to the defendant a statement of the cause of death, which, if true, vitiated the policy. The statement was embodied in a physician's certificate. If it had been contained in the guardian's own statement, or that of any nonprofessional person, it would equally have been an admission of the fact stated. The certificate was a part of the proofs furnished. Its admission in evidence violated no confidence. The confidence had already been violated by the conjoint action of the physician and the guardian. It was not offered as independent evidence of any fact in the case, but in connection with the circumstances of its transmission to the company, as an admission that the fact alleged was true."

CLAIMED NEGLIGENT TREATMENT OF FRACTURE OF FEMUR

The plaintiff in this case, an unusually large man sixty years of age, over six feet in height and weighing about two hundred and eighty pounds, sustained an injury by falling from a scaffold. He was taken to a nearby hospital where *x*-rays showed a fracture of the right femur. The patient's leg was placed in a temporary splint by a member of the hospital staff. The defendant doctor was called in to take charge of the case and, after making a superficial examination, caused the patient to be removed to another nearby hospital with which he was associated in order that he might better be able to care for the case. A further *x*-ray examination was had and the diagnosis was a simple fracture of the shaft of the femur at about its midway point.

On this same day the patient was placed in a fracture bed, where traction and counter-traction for lateral displacement were applied. The amount of traction applied was fifteen pounds which, owing to the tremendous weight of the patient, was later increased to twenty pounds. This treatment gradually exhausted the muscles in the region of the fracture, and finally the bone fragments were caused to come into alignment.

After over a week of this mode of treatment, during which time a series of *x*-rays were taken, the defendant doctor caused the extension to be taken off and the patient to be sent to the operating room. At that time the muscles were so exhausted that when the patient was laid flat there was no necessity for temporary extension. The doctor placed the patient on a Hawley table,

fastened both legs in the foot receptacles and straightened the legs until measurements were the same. An *x*-ray was then taken which showed coaptation and good alignment of the bone, and a plaster of Paris cast was applied extending almost to the waist including the pelvis, and down the leg to the foot. The next day the cast, as a matter of routine, was cut away slightly to better enable the patient to rest more comfortably.

The patient continued under the doctor's care at the hospital for about two and a half weeks from the time the cast was applied, when he was allowed to return to his home, the leg, however, remaining in the cast. The man was a very nervous type and continually complained that the cast troubled him and demanded its removal. The defendant doctor explained that early removal of the cast might very likely cause a divergence of the bone, but the patient was insistent, and the doctor removed the cast after it had been on the leg for six weeks and warned the patient that in his judgment the cast should have remained on for a longer period.

The patient remained in bed under the care of the defendant; and about three weeks later, by palpation and comparison with the other leg, an outward bowing at the seat of the fracture was observed. The doctor made an attempt to straighten out the fracture, manipulating the leg under forceable pressure, but without success. The patient was warned that the only reasonably sure way to prevent shortening was to submit to an open operation. This he refused. The doctor decided against another cast, feeling it would be useless because of the patient's opposition. The patient's condition improved, and the end result when the doctor last saw the case was fairly good except for some bowing and shortening.

Some time later suit was brought against the defendant doctor, claiming that he was negligent in his treatment of the case and that he was responsible for an overriding and overlapping of the fragments of the bone which greatly shortened the leg and impaired its use. The case duly came on for trial, and when directed by the court to proceed the plaintiff's attorney was not ready, although the defendant and his witnesses were in court prepared to commence the trial. Judgment for the defendant was then directed by the court, thus terminating the action in the doctor's favor.

ALLEGED MALPRACTICE IN TREATING STAB WOUND

In this case the doctor, a general surgeon, was called to the home of a girl, about twelve years of age, to treat her for a stab wound on the left knee joint. The doctor was told that the child's younger brother, in a fit of anger, had run the point of a pair of rusty and dirty scissors into the girl's leg. He observed that the child was bleeding profusely from the arteries. The doctor after sterilizing the necessary instruments by boiling them in the family tea kettle on a gas stove for about twenty minutes, proceeded to treat the wound. He first sterilized the wound with iodine and then clamped the arteries with sterile clamps, and proceeded to suture the bleeding points with sterile catgut. The lower end of the wound was left open for drainage, more iodine applied, a wad of sterile gauze placed on the wound, and a bandage wound around the leg. The child's mother told the doctor that he should not call again unless she notified him.

About five days later the doctor was called back and found the wound infected, and considerable swelling present. With sterile instruments, boiled as before, the doctor opened the sutures and put in a gauze counter drain about two inches above the wound. A wet dressing of boric acid was applied.

The next day he again returned and found the condition to have improved. He then removed the drain, washed out the wound with peroxide and inserted a new drain. On that occasion he advised the child's mother that he felt he should dress the wound daily for a number of days, but she pleaded poverty and told him not to call unless requested.

Subsequently a suit was instituted on behalf of the child, claiming that the treatment given was negligent and that the doctor was responsible for the infection. It was claimed the condition became worse to the extent that the child was taken to a hospital and extensive incisions were necessary to clear up the infection.

In addition to charging the doctor with liability for pain and suffering the complaint charged that he was the cause of the child sustaining disfiguring scars. The case was duly brought on for trial, but when reached the plaintiff's lawyer was not ready to proceed, so on motion of the doctor's attorney the action was dismissed.

NEWS NOTES

LEGISLATION

FINAL BULLETIN—MAY 9, 1931

The Governor has disposed of the last of the bills left with him by the legislature at its close and we are, therefore, in a position to give you a final statement of the activities of the legislature of 1931.

First, let us briefly review those bills which failed to pass, some of which we worked to defeat:

The osteopaths, sensing that their bill would be rejected after a hearing accorded it by the Assembly Education Committee, amended it almost to the form that it had last year, succeeded in having it passed by the Senate, tabled by the Assembly, and finally failed by one vote to have it taken from the table. They are already planning their campaign for next year.

The chiropractic bill passed the Assembly with a majority of two votes, but was able to muster only twelve votes in the Senate. The physiotherapists failed to bring their bill from the Education Committee in the Assembly, and later joined with the chiropractors in an effort to have that bill passed. It is to be presumed that many of those who are practicing physiotherapy could qualify as chiropractors under the bill that was before the legislature this year.

The anti-vaccination bill was given a hearing before the joint Health Committees, but failed to be reported out in either house. The anti-vivisection bill was accorded a hearing by the Assembly Codes Committee and was defeated.

All of the occupational disease bills were defeated, as well as the bills providing for free choice of physician by injured employee.

The Wicks-Hutchinson bill, which resulted from the Governor's Health Commission's investigation, after being given a hearing by the joint Finance Committees, was amended so that it carried only the provisions for the construction of three tuberculosis hospitals, an increase of the Department of Health by the addition of two divisions, and the treatment of venereal diseases. Another portion of the original bill, providing for the transfer and financial control of Haverstraw and Ray Brook hospitals to the Department of Health, was reintroduced and passed. Still another portion of the original Wicks-Hutchinson bill, also introduced as a separate bill by Mr. Wicks and Mr. Hutchinson, outlining the duties of the Public Health Council, etc., failed of passage. A recommendation of the Governor's Special Health Commission that health officers in cities with a population above 50,000 should be full-time employees, was incorporated in a and passed both houses after being amende read "hereafter appointed."

Among the other bills that passed, in w we had a special interest, were the Hartshorn which places industrial clinics under the in tion and supervision of the Department of S Welfare, and a bill by Senator Fearon w authorizes the Department of Social Welfa make inspection and rules and regulations fc hospitals, whether privately operated or ac ing public funds.

May we express our appreciation of the pr and enthusiastic cooperation received from chairmen of the various county committees year. A larger number than in any prece year took a very active interest in what we doing. Unfortunately, we must admit that are still some who must receive our bulletins from whom we never hear the opinions of physicians in their counties. We have a sug tion, however, that we think would increase efficiency of all of the committees, and th that the chairmen devise a way of passin members of their County Societies the info tion sent out by us in our bulletins. We ca put every physician on our mailing list; and other method of reaching the physicians thr the columns of the Journal, is of necessity n delayed. The Journal prints our bulletin promptly as they are received, but if the bul reaches them at the latest moment that it can publication, it will still be more than a week fore the physicians can read it. We need prc and hearty cooperation in order to forestall active cults, and we hope that each chairman give the matter his careful consideration and vise a plan by which he can improve his ser with us next year.

A list of the bills signed by the Governor lows:

Senate Int. No. 441-Hickey; Assembly No. 727-Piper; amending Education Law to mit employment of optometrists and oculists examining children in public schools. Cha No. 133 of the Laws of 1931.

Senate Int. No. 1047-Cheney; Assembly No. 1407-Piper; amending Public Health Lav increasing fees of registrars of vital statis Chapter No. 265.

Senate Int. No. 1256-Hofstadter; Asser Int. No. 1630-Austin; amending Mental Hyg Law for removal or commitment of insane

apparently insane persons for care, treatment or observation for limited period, to psychopathic wards. Chapter No. 366.

Senate Int. No. 1354-Fearon, amending State Charities Law and Membership Corporation Law, relative to corporations operating under rules of or requiring approval of State Social Welfare Department. Chapter No. 454.

Assembly Int. No. 377-Fitzgerald; Senate Int. No. 1325-Lord; amending Tax Law by providing property belonging to medical societies in Queens County may be exempted from taxation up to $150,000. Chapter No. 433.

Assembly Int. No. 531-Hewitt; Senate Int. No. 377-Campbell; amending County Law by giving coroner a fee of $1.00 for reporting to motor vehicles commissioner concerning a death found to have been result of a motor vehicle accident. Chapter No. 52.

Assembly Int. No. 573-Dickey; Health Law, making it violation of article to possess pipes, lamps and other apparatus for the use of opium. Chapter No. 479.

Assembly Int. No. 574-Dickey; making it violation of article to obtain habit-forming drugs from one physician while receiving treatment from another without disclosing the fact. Chapter No. 480.

Assembly Int. No. 1362-Hutchinson; amending Public Health Law, State Charities Law and Public Welfare Law, relative to tuberculosis hospitals, care of patients, and to other institutions, and appropriating $750,000.00. Chapter No. 481.

Assembly Int. No. 1453-Bentley; Senate Int. No. 1080-Wicks; authorizes Greene County supervisors to establish a public general hospital. Chapter No. 132.

Assembly Int. No. 1724-McKay; amending Education Law by prohibiting the practicing of optometry from house to house or on streets or highways. Chapter No. 375.

Assembly Int. No. 1865-F. L. Porter; Senate Int. No. 1345-Brereton; amending Public Health Law by providing appointment by health officers, of public health nurses, must be approved by district health board. Chapter No. 416.

Assembly Int. No. 1887-Gimbrone; Senate Int. No. 1319-Wicks; Public Health Law, requiring health officers in cities of more than 50,000 to devote entire time to duties of office and not engage in practice of medicine. Chapter No. 473.

Assembly Int. No. 1955-Austin; Senate Int. No. 1469-Wicks; amending Public Health Law by giving county health commissioner equal authority with a local board to investigate and abate public nuisances affecting health. Chapter No. 288.

Assembly Int. No. 1981-C. P. Miller; Senate Int. No. 1491-Gates; amending Workmen's Compensation Law by providing board may within three years instead of one from date of accident, reclassify a disability. Chapter No. 292.

Assembly Int. No. 2017-Rice; Senate Int. No. 1511-Webb; amending Education Law relative to physically handicapped children. Chapter No. 297.

Assembly Int. No. 2037-Hartshorn; Senate Int. No. 1762-Wicks; amending State Charities Law relative to prohibition against use of drug stores as dispensaries. Chapter No. 364.

Assembly Int. No. 2132-C. P. Miller; Senate Int. No. 1625-Gates; amending Workmen's Compensation Law by providing time limit for contracting disease under this section shall not bar compensation in case of employee who contracted disease in employment with same employer by whom he was employed at time of disablement. Chapter No. 344.

Assembly Int. No. 2290-Hutchinson; Senate Int. No. 1843-Wicks; relative to fiscal supervision of state reconstruction home at West Haverstraw and hospital for treating incipient pulmonary tuberculosis at Ray Brook, and transferring appropriations made therefor. Chapter No. 453.

HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY,
Committee on Legislation,
Medical Society of the State of New York.

THE COUNTY SOCIETY IN VENEREAL DISEASE CONTROL

In response to a request from the State Commissioner of Health to the Medical Society of the State of New York, that the State Society give aid in an effort to lessen venereal disease in this State and appoint a member of the Society to act in conjunction with the Director of Social Hygiene in. the State Health Department, your Executive Committee appointed Dr. J. N. Vander Veer to act as such liaison officer and to report back from time to time the progress made.

As no program was formulated and the way was free to plan, your representative has had numerous conferences with Dr. Pfeiffer, Director of the Division of Venereal Diseases, and from them many avenues have opened up wherein the general practitioner should benefit in every way, if the plans can but be matured, though it is not to be surmised that all will be done in a week or even months.

From a recent set of statistics collected by Dr. Pfeiffer, it has been shown:

1. In the Treatment of Syphilis alone about four persons per thousand, or nearly one-half million persons in the United States are constantly under treatment on account of syphilis.

2 Slightly more than one-third of these cases are in the early stages of the disease, viz the disease has developed within the preceding year

3 The rate in urban areas is five times greater than in the rural districts

4. Sixty per cent of all syphilis cases are being treated by private practitioners and the remaining forty per cent in clinics, hospitals and state institutions

5 Forty per cent of physicians are treating one or more cases, but ten per cent of physicians are treating two-thirds of all privately treated cases, and five per cent are treating one-half of all the cases, while one per cent are treating one quarter of all the cases

6 In other words, of 100 cases being treated, thirty per cent are being treated by general practitioners, thirty per cent by specialists, and the remaining forty per cent at public expense

These figures recently compiled by Dr Pfeiffer from a large list of questionnaires sent to practitioners and specialists in this State, in which ninety per cent returned answers, may astound many physicians who have believed that the vast majority of syphilitics were being treated in hospitals, institutions and clinics

It is with these sixty plus per cent and some of the forty per cent, who should be in the hands of the private practitioner, that your Society desires to interest itself in mostly, and next to see that that part of the sixty plus per cent which leaves the private practitioner to seek out a clinic or dispensary, or gives up treatment entirely for economic and other reasons, is cared for in a preventive way, either by return to the private practitioner where that is possible, or to a dispensary or to a clinic, that the drive for amelioration or subjugation of this and later other venereal diseases, be through the cooperation of the State Health Department and your State Society with the private practitioner and vice versa

The fact that only one-third of those coming within a given month to private practitioners, to dispensaries, and to clinics, are in the early and easily curable stage, and that this disease is slightly on an increase, shows a lack of knowledge on the part of the laity as to the likelihood of the disease present among them, or to the laxness of their seeking treatment, and to the laxity or carelessness on the part of the physician in early diagnosis of the initial lesion, or inability to diagnose the disease in its early stage

Upon this basis your Medical Society believes you, as a County Society, should enter into cooperation with the lay bodies, whose duty it shall be to inform the public of the prevalence of the disease and urge patients to seek diagnosis and treatment at the hands of the private practitioner first, and if this is impossible economically, then your Society give aid in hospitals and clinics, or through the local Health Officer

The Medical Society also believes that the Health Department should cooperate in keeping the patient under treatment at the hands of the private practitioner, and where that is impossible should see that dispensaries or clinics are provided and a follow-up system made possible, and even later to plan for a follow-up system which may be utilized in any City or Community by the practitioner to see that his private patients, or semi-private ones, and as now provided in the new Law, and by the local Health Officer for those unable to pay, and their contacts do not err in abandoning treatment

It is later planned, if possible, for the Health Department to furnish more drugs to private practitioners as well as now is done with a few drugs for indigent patients, in the eagerness to overcome this disease, which in the present day from reliable statistics seems to show that deaths from cardiovascular and neurosyphilis now exceed those from tuberculosis Of this, Dr Pfeiffer can speak with authority

If such an effort can be rightly directed, then the physician, and organized medicine, can but rejoice that the three great bodies for the conservation of good health and the eradication of disease, at least in this one disease, have united on common ground

But the medical profession must do its part in self education, received through your State Society's Post Graduate Course In some places, general practitioners are doing yeomen's work without remuneration, where monetary reward should be theirs for time expended Here is where the State Health Department, in cooperation with the Public Relations Committee of the County Society, can spur the lay organizations to unite and see that the Boards of Health, or Boards of Supervisors, include in their budget remuneration for such medical workers

Again there are places in the State where local practitioners are receiving pay for their services as directors or workers in dispensaries or clinics, and who give but meagerly of their time, but make sure of their pay check, having as well at their command, technicians and helpers This is not right, for it is but fair that those who seek the emolument should give fairly of their time, as examples for the younger practitioner, who believes he is being crowded out by the older man

Too many of the clinics are over crowded and under manned, and yet should the local groups of Health Officer, Lay Group and County Society unite in a given move to bring some pay to the younger practitioner in the community for giving part of his time to that clinic, then throughout the State the entire medical profession would benefit economically, the public menace of the syphilitic, especially of the non-paying type, would be better controlled, and the disease brought nearer to eradication.

Organized medicine took a large step forward in the award made to it economically in the Public Welfare Law; and the opportunities now given it for further advancement economically and professionally should not be laid aside, and its enforcement lies with your Public Health Committee, and your own Public Relations Committee in dealing with your own local and new Public Welfare Officer.

When the profession itself passes up the opportunity to do its share, aided by the State Government, and to be paid by your local government for services rendered as individuals, then it should not complain when the State Government steps in to protect its people from the increasing inroads of diseases such as now are being fought.

The brunt of the fight must be borne by the individual doctor, for he it is who sees the case first, and can make or delay, or even negate a cure if he is slothful at his first contact; while to him will come the credit and respect of the community when it permeates through the same that he is careful, painstaking and successful, and his reward can be turned into dollars so soon as that community can be brought to recognize his value.

It is with the diagnosis properly of the primary sore by the first physician seeing it, who lays aside his petty jealousy and has the sore diagnosed by the dark field method, that our combined hope lies.

Where the physician fails to grasp such a reward, then the State will step in to do its share, but only after painstaking effort to have the general practitioner do his part. Remember the gonorrheic! A Wasserman every two weeks for three times to ferret out the cases of intro urethral chancre!

Where the doctor may receive his remuneration direct from his patient, or in indigent cases from the community, then is the State relieved of this financial burden, which has so been placed where it belongs, together with the responsiblity of seeing that the patient is carried through to a complete cure or to sterilization.

But doctors are not in a financial position to employ a follow-up system for their cases, and so here enters in the duty of the community through its local health governing board, or through its local charity group, or even perhaps through the State Health Department to provide full time, part-time, or intermittent survey and follow-up of the venerite.

Where the financial burden is too great for the patient, then the community or the local health governing group must provide facilities for treatment of this disease, extending even to partial or total remuneration of the attendent physician, as well as for the place; equipment, etc., where the patients are to be treated.

Few local communities, or local health departments have the facilities to follow up the lapsed cases, and so they drift along until late cardio-vascular complications present themselves, too late to be afforded much help from treatment.

Your State Society therefore seeks the aid of four groups:

1. The Physicians of each community to urge upon that community the providing of a follow-up nurse for these diseases in individuals when called upon so to do by *any physician* in that given area. Such a nurse might give time to other health activities also.

2. If the local lay groups cannot find the means so to employ a nurse, through the efforts of the Public Relations Committee of the County Society, and their own liason Committee, the Red Cross or other health welfare groups, and through the aid of the local Health Officer, in the interest of the local peoples, and to be supported by local funds, then the State Society asks the Public Relations Committee of that County Society, to cooperate with the local Health Officer and urge upon the State Department of Health the providing and placing of a follow-up nurse in that district to assist the local physicians, when she may be so called upon, to seek out the cases which have neglected treatment, and bring them back to their original physician, and to take up treatment again, or to compel them to report to the local health officer, who must provide treatment. In the rural districts the cases would seem to average but 0.53 per thousand, while in the urban districts this runs up to 2.41 per thousand. A nurse therefore is not needed in the rural districts. on full time, to interview the cases, as not all physicians would need her services and the cases are too few—save as distance in travel might consume time—hence her service could be utilized elsewhere.

3. The Public Health Committee, and the Public Relations Committee of each County

Society shall attempt the enlistment and aid of local groups in the smaller cities, in towns and in villages in the establishment of a first aid station, a dispensary, or similar provision, where equipment could be housed for the diagnosis and treatment of such diseases, as well as for using the station for many other medical purposes. These first aid stations should be under a joint management of the local medical representative, the local health officer and the lay group of that vicinity, whose duty it might be to see that emergency and treatment equipment, for these diseases especially, as well as for many of the local diseases and injuries, was provided.

4. In the smaller cities and towns to try and interest the younger men in utilizing these first aid stations on hourly or part-time basis or in rotation, in attendance upon the indigent who might be sent there by other practitioners, the health officer, nurses of the district school or health officer, the public welfare officer and others, where quick and efficient diagnosis of that first sore may be made; and further to make effort that these younger men be remunerated by the local community for their time so expended, and thus interest themselves in becoming rooted to the local soil, and yet having economical independence

JAMES N. VANDER VEER, *Albany, N. Y.*

WASHINGTON COUNTY

The semi-annual meeting of the Medical Society of the County of Washington was held at Cambridge at 4 p. m. May 12, 1931. The meeting was called to order at 4 p. m.

Members present: Drs. Prescott, Munson, Leonard, Hulst, Park, Falkenbury, Cuthbert, Rogers, Borrowman, MacArthur, Bailey, Paris, Stillman, Casey, Banker, Holmes, Gillette, Fortune, Johnson, Bennett, Sumner, Vickers. Visitors: Dr. Frank vander Bogert, Schenectady; Dr. Kingsley Roberts, New York; Dr. George E. Smith and Dr. Clayton E. Shaw, Hoosic Falls.

An afternoon session was held at 4 o'clock and an evening meeting after a social supper.

The Treasurer's report shows $116.48 available for the society. Dr. Banker stated that the NEW YORK STATE JOURNAL OF MEDICINE had been bound and placed in the Mary McClellan Hospital up to 1930, and a motion was adopted that we have each year bound from now on.

A motion was carried that we accept the agreement with the insurance carriers as arranged by our economic committee.

Dr. Rogers presented his report as chairman of the public health and economic committee consisting of a medical survey of the county, which was placed on file. He stated that he attended the conference of Committee Chairmen and thought that the work in our county compared very favorably with the reports of other counties. He advised that we should urge upon the boards of education the importance of smallpox vaccination in school children. Dr. Rogers has been very faithful in his work the past five years, and the members showed their appreciation by giving him a vote of thanks.

Dr. Leonard presented his report as chairman of the legislative committee. The doctor has in the past five years become familiar with legislative matters and gave us a very exhaustive report.

It was largely through his efforts that the county health bill in its initial form was defeated, and in appreciation of his work the society gave him a vote of thanks. At the suggestion of the doctor, the secretary was requested to write a letter of commendation to our senator and assemblyman for their support of the medical profession.

The Doctor also presented the following resolution, which was adopted:

Resolved, that the Medical Society of the County of Washington hereby declares itself in favor of the principle of County Boards of Health, and be it further

Resolved, that the delegate of this society be instructed to support a resolution introduced in the House of Delegates of the State Society at the next meeting of the Society, which shall have for its object the reorganization of the Public Health Administration of the State on the plan of County Health boards, provided that such plan is approved by such representatives of the State Department of Health, The State Medical Society, the State Sanitary Officers' Association, and of other interested groups as shall have been delegated power to formulate such a plan.

Dr. Falkenbury presented a paper on Fractures, and stressed the importance of extension in the reduction of the same. Dr. Bailey discussed the paper and presented a case of ununited fracture of the femur.

Dr. Munson presented his paper "The Practicability of Epidemiological Investigation in Syphilis and Gonorrhea. He showed the importance of tracing the source of these diseases.

Dr. Gillette presented his paper "Diathermy in the Production of Therapeutic Fever."

Dr. Vickers presented his paper "Spinal Anesthesia." He said it was a very useful addition to our list of anesthetics, but was not applicable to all cases.

Dr. Kingsley Roberts of New York gave a practical paper on "Chronic Cholecystitis."

Dr. Frank vander Bogert of Schenectady discussed the "Feeding of Sick Children."

S. J. BANKER, *Secretary.*

THE DAILY PRESS

Reg'lar Fellers — Can't Help Himself — By Gene Byrnes

From the New York Herald Tribune, April 28, 1931.

The relation of clean hands to washing dishes seems to be a favorite bit of humor for the cartoonists, for this same joke in a slightly different form appeared in the *New York Herald-Tribune* of August 1, 1930, and was reproduced in the NEW YORK STATE JOURNAL OF MEDICINE of November 1, 1930, page 1311. The question sometimes arises as to what constitutes a good medical joke. This one would seem to deserve that title.

MANGANESE AND TEMPERAMENT

Recent reports in the newspapers on the effects of manganese in food may be either half way scientific or semi-humorous; but there is no doubt about the intention of James J. Montague to be funny in the following verses in the *New York Herald Tribune* of April 28:

"When Willie sates the wild desire,
Which wayward urchins often feel
To set the tablecloth on fire
While lapping up the noonday meal,
While mother smiles her approbation
And says, "The child is such a tease!"
It merely is an indication
That she'd had too much manganese.

When Willie, absent from the schoolroom
A few years on in his career,
Is found around the village poolroom
Consuming mugs of foaming beer,
And mother says, 'Poor, pestered creature,
He has to have his little larks;
He's driven to them by his teacher,'
You know what prompted her remarks.

When, grown to manhood, Willie's passion
Is strutting proudly up and down,
The mirror of the glass of fashion
The haberdasher keeps downtown,
And mother thinks that he's a wonder
Of elegance and idle ease,
It merely shows that she is under
The influence of manganese.

This element, it seems, like whisky,
Consumed too avidly, can be
To those who eat of it quite risky
Unless prescribed by an M. D.
And often Algernon and Clarence
Turn out weak limbs of sturdy trees
Because their overdoting parents
Could not keep off the manganese."

A KING'S CATARACT

The Medical Society of the County of New York and the New York Academy of Medicine jointly support a medical information bureau for the purpose of giving out medical information that is correct from the doctors' point of view When the King of Siam underwent an operation for cataract, the Associated Press recognized the world-wide interest of the people of all lands and asked Dr. Iago Galston, the Executive Secretary of the Bureau, to be present at the operation and to describe it for the press Dr Galston's excellent report is printed in the New York *Times* of May 1st, as follows

"The cataract of the eye, for the removal of which King Prajadhipok of Siam has come to the United States, while not presenting a serious surgical problem, is interesting from the medical point of view in that it should occur in so young a man.

"King Prajadhipok is 38 years old Cataracts among the aged are rather common

"Both eyes of the King are affected The cataract in the left eye, which has been developing for six years, is now ripe for removal The cataract in the right eye is not yet ready for surgical treatment There is no way of getting rid of cataracts except by operation

"The term cataract is used to indicate a condition where the crystalline lens of the eye becomes clouded In the operation the entire clouded lens is removed After the operation the patient is equipped with a glass lens worn as spectacles on a frame, to take the place of the lens that has been removed The operation should result in normal, or nearly normal vision

"The exact cause of uncomplicated cataract is unknown, but one of the causative factors is some interference with the nutrition of the crystalline lens

"As the King is also a sufferer from hay fever and asthma, he will undergo a series of tests and treatments by Dr Robert A Cooke to determine his possible susceptibility to the dusts and pollens about the Ophir Hall estate in Westchester, and his constitution will be built up to withstand any possible attacks"

DETERMINANTS OF HEREDITY

The New York *Times* of April 29 has the following bit of scientific news which is of interest to doctors and scientific research workers rather than laymen

"Dr Albert F Blakeslee told the National Academy of Sciences today that characteristics of the whole present human race were decided by bits of matter that altogether weigh less than a pin or drop of water

"This is approximately the weight he said, of the chromosomes that existed in the original cells from which the billion and a half people now on earth developed The exact weight would be about forty-four millionths of a pound Chromosomes are microscopic objects within living cells by means of which human characteristics are handed on from one generation to another

"Dr Blakeslee described a new method for locating genes within particular chromosomes developed at the Carnegie station for experimental evolution at Cold Spring Harbor, N Y, with which he is connected"

STATE DENTAL ASSOCIATION

The New York State Dental Association held its sixty-third annual meeting in the Hotel Pennsylvania, New York City, during the week beginning May 11, and its proceedings were noted in the daily papers The New York *Times* of May 13 mentioned the following papers that were read on the previous day.

"Dr McWinterwitz, Dean of the Yale University Medical College placed the dentist on an equal professional footing with throat, eye, and other specialists

"Dr H E Friesell, Dean of the University of Pittsburgh Dental College, declared no profession had a greater responsibility to humanity than dentistry He said it was the duty of the dental profession to work out some means of providing dental care for those unable to afford treatment

"President Hoover sent a message commending the society for 'furthering the ideals set forth by the White House Conference on Child Health and Protection'

"Dr Walker, President of the State Association, in his annual address stressed the need for a program of pre-natal care and early, regular and frequent attention to the pre school child, to prevent dental disease"

It would seem that there should be a close contact between the State Dental Association and the State Medical Society

BOOK REVIEWS

PIERSOL'S HUMAN ANATOMY: Including Structure and Development and Practical Considerations. Ninth Edition revised under the supervision of G. Carl Huber, M.D., Sc.D. Quarto of 2104 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1930. Cloth, $10.00.

An accurate comprehensive volume on human anatomy of special interest to the graduate student, but perhaps too large for the undergraduate. The descriptions are lucid and complete. The illustrations are numerous and well placed. One is indeed impressed by the meticulous attention to details in every drawing, colored or uncolored. But perhaps a more definite attempt toward more intense coloring, with a suggestion of the third dimension, would be of material assistance in developing one's coefficient of visibility. For a distinct visual sense is a sine qua non in storing anatomical facts.

The sections on embryology and osteology are very complete and well written. Of definite value to the progressive physician and surgeon are the chapters on "Practical Considerations." Here one obtains real anatomical aids briefly but thoroughly written. The salient features of each problem are clarified from a structural viewpoint.

An anatomy is incomplete if the fascial planes are incompletely or inaccurately delineated and described. From the superficial fascia of the scalp down to the plantar fascia, this mesodermic tissue is carefully traced, whether in the cervical, lumbar or inguinal regions.

The division on neuro-anatomy is so comprehensive, that one is awed in contemplating the stupendous task the writing of this book entailed. It is an excellent reference book for the modern doctor.

ALFRED H. IASON.

OUR NEW PROGRESS. Two Essays—Cornucopia and Caritas. By JAMES BAYARD CLARK. Octavo of 128 pages. New York: London, G. P. Putnam's Son's, 1930. Cloth, $2.00.

In these two essays, Cornucopia and Caritas, Dr. Clark, departing from the urological paths along which he has strolled for so many years, enters the domains of sociology and economics and displays much uncanny insight in his analyses of prosperity and charity. We do not believe he has ever pursued a culpable colon bacillus with anything like the ardor he puts into his philanthropist hunt. He traces the origin of the system under which we live and finds that charity is the natural result of exploitation when Puritanism influences the plutocrat. Puritanism blessed the man of flocks and herds, and prosperity became a measure of Jehovah's affection. Very good, but the same Puritanism decreed that he could not enjoy his spoils in pagan fashion. Faced by this dilemma, the plutocrat is forced to disgorge in the modern manner, that is, he establishes Foundations and medical schools, subsidizes education and, worst of all, engages in philanthropy, from which activities flow most of our ills to-day. Dr. Clark works out his thesis in a capable way and the doctor who is interested in sociology and economics in so far as they affect medicine will find much to absorb him in Dr. Clark's little book. But while his diagnostic methods are impressive he offers but little in the way of treatment. He does not know what is going to become of our trick educational system and our trick kindness to the poor and the sick. The last paragraph of his book confesses impotence, tinged with a wistful optimism.

A. C. J.

OPERATIVE GYNECOLOGY. By HARRY STURGEON CROSSEN, M.D., F.A.C.S. and ROBERT JAMES CROSSEN, M.D. Fourth Edition. Octavo of 1078 pages, illustrated. St. Louis, C. V. Mosby Company, 1930. Cloth, $15.00.

Crossen's Operative Gynecology is so well known as a standard work on gynecological operative technique that it needs but little introduction. The fourth edition contains many changes, and the subject matter has been brought up to date and systematized for helpful presentation. Four new chapters have been added:—Genital Fistulæ, Diseases of the Urinary Tract in Relation to Pelvic Surgery, Diseases of the Intestinal Tract in Relation to Pelvic Surgery, and Anesthesia in Gynecologic Surgery.

The illustrations are excellent, and it is quite possible in many instances to grasp the technique of an operation without referring to the text.

The author describes the standard operations for conditions requiring operative treatment, and discusses the particular type of operation which is most applicable to certain types of cases.

The volume is excellent, and it is, not only a wonderful text-book, but it is a fine reference book, as well.

W. S. S.

CHRONIC ARTHRITIS AND RHEUMATOID AFFECTIONS with recovery record by BERNARD LANGDON WYATT, M.D., F.A.C.P. with collaboration of LOUIS I. DUBLIN, Ph.D. Octavo of 141 pages. New York, William Wood & Company, 1930. Cloth, $2.50.

This book is an excellent summary of our knowledge to date of chronic arthritis,—its etiology, preventative measures and diagnosis. He goes into extensive details as to the various measures and treatments, assigning each its proper place. There is a thorough discussion of diet, drugs, vaccine, non-specific proteins, hydrotherapy, colonic lavage, electric currents, radium heat, joint exercises, joint movement, massage, climate, sun baths, orthopedic measures and surgical treatment.

This book will well repay those who come in contact with the sufferers of chronic arthritis.

M. A. RABINOWITZ.

A MANUAL OF NORMAL PHYSICAL SIGNS. By WYNDHAM B. BLANTON, B.A., M.D. Second Edition. Octavo of 246 pages, illustrated. St. Louis, C. V. Mosby Company, 1930. Cloth, $3.00.

This classroom guide on normal physical signs is arranged in skeletal form to assist both teacher and student in making systematic progress. The notes are very much like those employed in most medical schools, but their arrangement in book form should serve as a ready reminder to the student who has been drilled into the contents of this not too colorful type of book.

EMANUEL KRIMSKY.

MINOR SURGERY AND BANDAGING. By GWYNNE WILLIAMS, M.S. 20th Edition. 12mo. of 445 pages, illustrated. Philadelphia, F. A. Davis Co., 1930. Flexible Cloth, $3.50.

This is the 20th edition of a book remarkable for its conciseness, accuracy and completeness. The house surgeon for whom the volume is primarily written can get satisfactory answers to all the varying questions that confront him in his daily work. The author has the rare faculty of supplying the best surgical information with a minimum of unessential detail in the best of the King's English.

GEO. WEBB.

PRACTICAL RADIATION THERAPY. By IRA I. KAPLAN, B.S., M.D. With a special chapter on applied x-rav physics by CARL B. BRAESTRUP, B.Sc., P.E. Octavo of 354 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.00.

This book of Dr. Kaplan's may be divided into two portions. The first section is largely historical and also deals with radium and Roentgen physics. The section by Braestrup on "Applied X-ray Physics" is especially commendable for its completeness and clearness.

What may be considered the second section is the practical application of radiology in disease. This is written in an intimate and informal manner and the giving of the technique which has been found to have been most effective in the author's large experience at Bellevue Hospital, New York, is of especial value.

The publisher's work—paper, printing and illustrations—is splendidly executed.

The whole work is most useful as a guide to radiotherapeutic practice and the author has well fulfilled his purpose as given in the Foreword "to state, as simply as possible, the established principles of radiation therapy and the methods for carrying out this form of treatment." C. E.

INTESTINAL TOXEMIA (Autointoxication) Biologically Considered. By ANTHONY BASSLER, M.D. Octavo of 433 pages, illustrated. Philadelphia, F. A. Davis Company, 1930. Cloth, $6.00.

Dr. Bassler has written an extensive treatise on autointoxication, or as he calls it—"intestinal toxemia" Much of the writer's attention is devoted in exposing such commercialized fads as yeast, Bulgaricus milk, Acidophilus milk, colon irrigations, and patent medicines He makes a sharp distinction between constipation and intestinal toxemia and regards them as often being independent of one another. He speculates on the relationship of intestinal toxemia to other diseases and admits that proof is very difficult.

Several chapters deal with the biological characteristics of multitudes of intestinal organisms—a truly bewildering array. The writer evidently has faith in vaccines as a means of treatment even though it has not been successful with others.

EMANUEL KRIMSKY

DOCTORS AND SPECIALISTS. By MORRIS FISHBEIN, M.D. 12mo of 118 pages, illustrated. Indianapolis, Bobbs-Merrill Company, 1930. Cloth, $1.00.

In his most recent book, "Doctors and Specialists," Dr. Fishbein has staged a variety show and has given his audience of general practitioners ample opportunity to laugh with and at their specialist-actors. And even though he recommends this little book "to every doctor with a sense of humor" it also evokes another type of laugh due to satire. He respects his audience, especially the old-time physician and is convinced that his "good points are too many." He forgives him for some of his weaknesses, especially his prescriptions which often "had a kick like an overcranked Ford." But what will our successors think of our modern anaphylactic reactions. Even to this day sick ones live in spite of untoward remedies.

Some of his specialists are devoid of humor. The tonsil specialists he places in the same efficiency class with the Ford organization. He regards the surgeon as good-natured because he always agrees to a surgical diagnosis. And so while Dr. Fishbein sets out to feed his readers with humor he also succeeds in exposing some of the shortcomings of a specialty practice.

EMANUEL KRIMSKY.

PHYSICAL DIAGNOSIS. By WARREN P. ELMER, B.S., M.D., and W. D. ROSE, M.D. Sixth Edition. Octavo of 903 pages, illustrated. St. Louis, C. V. Mosby Company, 1930. Cloth, $10.00.

This new book on physical diagnosis by Elmer and Rose is a 900-page work and offers to the medical student and practising physician a fairly thorough consideration on that subject. Its method of presentation and its contents are by no means novel, and are not much unlike other standard works on the subject. The various familiar physical disturbances induced by disease processes are so numerous that the natural temptation for the serious reader is to supplement much of this information by referring to individual works on the respective topics. The book also serves as a reminder for refreshing oneself on forgotten facts.

It is becoming increasingly evident that the X-ray is relied upon more and more in attempting to confirm physical findings and in a number of instances X-ray findings are interpreted in conjunction with the routine inspection, palpation, percussion, and auscultation

EMANUEL KRIMSKY.

OUR NEIGHBORS

LEGISLATIVE HONORS TO MICHIGAN PHYSICIANS

A supplement to the May number of the Journal of the Michigan State Medical Society contains the stenographic minutes of a joint session of the two houses of the Legislature of Michigan held on April 14 to honor three professors of the University of Michigan for their contributions to medicine. These three doctors were Dr. Frederick G. Novy, chairman of the executive committee of the department of medicine and surgery of the University of Michigan; Dr. Moses Gomberg, professor of organic chemistry at the University; and Dr. Reuben L. Kahn, director of the laboratory of the University Hospital.

The legislators assembled at 4 o'clock and continued in session for two hours. The guests of the Legislature included the Judges of the Supreme Court and many other high officials of the State, including the Governor, the Hon. Wilber M. Brucker, who introduced the guests, the speakers and the honored doctors. In his own address the Governor said:

"I presume never in the history of the Legislature of this State has pause been taken for the purpose of stopping the legislative machinery during the last few weeks of its session when it is so busy, to pay this tribute of respect to anyone other than a member of the State government directly. We do have time to recognize these things that are quietly done, that are accomplishments of progress without all the spectacular drama, all the noise and flamboyancy of brass bands, but for the quiet industry who accomplish the things of the world.

"Today I would speak on the thought, in tribute to them, of the relationship of government and science. Science deals with exactness; it deals with precision, with accuracy. It deals with the things that are certain and definite; it deals with the things that are known and susceptible of important interpretation. It demonstrates itself through such instruments as the yard scale, the slide rule, measuring rod, arithmetical and geometrical formulas, and those things which are precise to a nicety and exact; which have boundary and limitation, which are circumscribed so the knowledge knows certain boundaries with which it is encompassed and beyond which man cannot go.

"Government, on the other hand, is just the opposite. Comparable with science it might be said in an analysis of those two, Government is the inexact, the unprecise, the speculative, problematical, theoretical; it deals largely with perspective and with the personality of individuals; with the reaction on human nature; and with such things as idealism, sometimes practical, sometimes impractical; with the enthusiasm, effort, and with things boundless in their scope without any limitation whatsoever, which are not susceptible of known knoweldge, but which, after all, must be a definite relationship called Science.

"We are met to honor Science more than Government today. Government owes a debt of gratitude to Science that it can never fully repay. Science has made possible the growth, the development of happiness, health and welfare.

"May I say just a word about the relationship of Science and Government? Hand and hand they have gone through the centuries and it is quite fitting and proper today that Science should bow its head to the blessings of Government, and Government should bow its head in recognition of the blessings of Science."

Dr. Alexander Ruthven, President of the University of Michigan, said:

"Universities have two objectives, the diffusion of knowledge, and the increase of knowledge.

"Knowledge is increased by research, which means simply investigation, study, the search for facts, principles and relationships.

"Mr. Ford's automobile; anti-toxin, electric lights, radio, ice machines, and those other accessories of civilization, are the product of research.

"The University is not only doing much for humanity in its shops, hospitals, laboratories and museums, but it is one of the great schools which believes in making the results of the study of its scholars available to the people of the State just as soon as possible."

Dr. Frederick G. Novy, one of the trio of physicians who were honored, gave a brief review of the practical results of medical research during the last half century, and said:

"Benjamin Franklin, standing in the garden of his home in Passail, outside of Paris, witnessed the first balloon ascend. At that time some one remarked to him: 'Of what use is that thing,' and his answer, well known to many of you, was: 'What use is a new-born child?' Time can only tell, and so it has been the story written high and large regarding scientific work.

"Not so many years ago, Pasteur was busy studying the germs causing fermentations. Anyone could have approached him then and said, 'Of what use is it to study this little organism

(Continued on page 722—adv. xiv)

Another Reason Why *Breast Milk* for babies *is Best Milk*

Recent investigations* indicate that breast milk contains a mysterious substance called lysozyme which has the power to dissolve air-borne and certain other adventitious bacteria that reach the infant's intestinal tract, this tract being sterile at birth.

Lysozyme also inhibits the growth of *B. coli* but has little effect on the desirable *B. bifidus* and allied types, and thus tends to stabilize the intestinal flora of the nursling.

No artificial feeding contains lysozyme. Only breast milk is blessed with this wise protection of Nature.

For almost thirty years, Mead Johnson & Company have recognized and urged the use of breast milk. As a second choice—where breast milk cannot be reestablished—we recommend cow's-milk-water-Dextri-Maltose formulae. When artificial feeding must be used, this system, while it does not supply lysozyme, does make possible a practically sterile feeding.

You can pasteurize the milk, you can boil the water, and you know that Dextri-Maltose is practically sterile. Not all carbohydrates are in this class. As a result of long experience in rigid sanitary control, Dextri-Maltose is a *clean* product rather than a *cleaned* product.

SYNTHETIC MILKS ARE NOT THE SAME AS BREAST MILK

The attitude of Mead Johnson & Company on the subject of synthetic substitutes for breast milk is in sharp contrast to the exaggerated claims of others that such synthetic milks are the equal of breast milk, to be used in every case. Mead Johnson & Company's Recolac is recommended only for traveling mothers and for complementing breast feedings in certain classes of cases where its use is quite defensible.

* Rosenthal, L. and Leberman, H: The rôle of lysozyme in the development of the intestinal flora of the new-born infant. J. Inf. Dis., 48:226 (1931). Copy of this paper and list of other bibliography available on request of Mead Johnson & Co.

Collosol MANGANESE

CROOKES

MANGANESE is one of the inorganic elements recommended for many years for blood regeneration and for the treatment of coccogenic affections, particularly Furunculosis, Boils, Acne, etc.

COLLOSOL MANGANESE 1-400 is extremely stable and does not precipitate on addition to the blood plasma.

Ampoules for intramuscular injection.

It is safe to inject and is almost totally free from the pain and discomfort attendant on the injection of solutions of manganese salts.

COLLOSOL MANGANESE is most successfully used intramuscularly, although some observers report favorable results from hypodermic injection. It has also a growing acceptance for oral use.

Vials for oral administration.

CROOKES LABORATORIES, Inc.

145 EAST 57TH STREET, NEW YORK CITY

CONCENTRATED POLLEN ANTIGEN

LEDERLE

RAGWEED COMBINED

For Fall Hay Fever

90% of all Hay Fever east of the Rocky Mountains is caused by the Ragweeds, Giant and Small. Thus the Hay Fever problem is simplified for the practising physician within this territory.

For the further convenience of the physician, Concentrated Pollen Antigen (Lederle) Ragweed Combined is now available in individual-dose syringes serially numbered. Each syringe contains an accurately measured dose ready for subcutaneous injection without dilution.

For 17 years Pollen Antigens Lederle have been successfully employed by general practitioners in the prevention and treatment of HAY FEVER.

Concentrated Pollen Antigen (Lederle) Ragweed Combined, *For Use Without Diluting*, is prepared by extracting the pure, mature pollen grains of Ragweed and Giant Ragweed 66⅔% glycerol and 33⅓% buffered saline solution. The extracts contain 0.4% phenol as a preservative. The individual-dose syringes are filled with an 0.2 cc. volume and permit the accurate injection of the entire dose or such division of the dose as may be desired. In these small doses, the 66⅔% glycerol with 33⅓% buffered saline may be injected subcutaneously without producing undesirable reactions.

Literature based on seventeen years experience and covering the main features of the Hay Fever problem will be furnished physicians upon request.

We also invite correspondence upon specific cases in any locality.

LEDERLE LABORATORIES Inc. NEW YORK

(*Continued from page 720*)

that you find under your microscope?' I can well conceive a shrug of the shoulders and a brief respone: 'Wait and see,' and it was not many years perhaps before that was realized.

"There is another aspect which I would like to call your attention to and that is this: It was supposed and believed that bacteria caused disease by contact; by being taken in water and the like. It never dawned, until the right time came, that there was another mode by which organisms could enter the body. Forty years ago, Smith in this country, by painstaking research, demonstrated that Texas fever in cattle was transmitted through the bites of ticks. That was something that had never been dreamed of before; that an insect could be responsible for a disease. It was so unusual that the scientists of Europe simply considered it an American way of pulling the wool; but it was not more than a half-dozen years, when the work of Ross in India showed that the malarial organism carried on its whole life history in the mosquito, and that malaria could not be contracted except through the bites of mosquitoes.

"In 1887, the Legislature of Michigan appropriated a modest sum of money for the establishment of the first hygienic laboratory in the United States. I take this occasion, particularly, to express my appreciation of that fact. It is the first institution, as I have said, of this kind. The idea was that Dr. Vaughan, who at that time was a member of the State Board of Health, and it is significant that the reasons for the establishment of that scientific laboratory were put down, first, research into the causation of disease; second, examination of waters and other materials to aid in the diagnosis of disease, and, third, that of teaching. Research was given the first prominent position. The University has endeavored to live up to that as its first objective."

When Dr. Moses Gomberg and Dr. Reuben L. Kahn were introduced, they merely expressed their thanks, thereby winning the praise of the Governor, "Very modestly done."

MEDICAL LICENSING BILL IN WISCONSIN

The *Wisconsin Medical Journal* of May devotes fourteen pages of small type to a description of a legislative hearing by the Assembly Committee on Public Welfare, held on March 18 and 25, to consider a bill modifying the composition of the Board of Medical Examiners. Mr. Crownhart, Secretary of the State Medical Society, said:

"The Wisconsin Board was created in 1897 with 3 allopaths (non-sectarians), 2 homeopaths and 2 eclectics; and then in 1915 when osteopathy

(*Continued on page 724—adv. xvi*)

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods — in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization — with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Fellows' Syrup contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants — strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

(*Continued from page 722—adv. xiv*)

was recognized in Wisconsin, one osteopath was added to the Board.

"In the original law the State Medical Society submitted the lists from whom the Governor made his selections of non-sectarian practitioners; the State Homeopathic Society, when appointments were due in the homeopathic field, would send in a list of names, and the State Eclectic Society for their two."

Mr. Crownhart exhibited a table of physicians licensed in Wisconsin in ten years, 1920-1930.

Non-sectarian (so-called Allopath)	1019
Homeopathic	8
Eclectic	1
Osteopaths	77

The number practicing in the State is now as follows:

Non-sectarian	2817
Homeopathic	139
Eclectic	44
Osteopathic	100

Mr. Crownhart describes the proposed bill as follows:

"The bill simply provides, instead of 3 allopathic, 2 homeopathic and 2 eclectic appointments as such, that the Governor shall appoint seven licensed to practice medicine and surgery in addition to the one osteopathic member, provision for which remains unchanged. So far as the State Medical Society is concerned, we are perfectly willing that if the Governor sees fit, he might appoint four eclectics and three homeopaths if he may choose them as representing the best in the medical profession of Wisconsin and not as representing classes, that, to our mind, have long since disappeared. We are willing in this measure to give the Governor the widest possible choice to the end of obtaining the best in the public interest."

Formal opposition to the bill was made by representatives of the Homeopaths, the Osteopaths, the Eclectics and the Chiropractors. A lawyer for the Osteopaths made a long plea for a continuation of what he called the old "balanced" board, and said:

"Here we have a medical board today that, as I understand it, stands unanimously against this bill. They know how that board is working even better than the Medical Society of the state—working in harmony for ten or fifteen years now, in perfect harmony, ten years at least, solving all these questions, doing justice to every school of healing and at the same time doing justice to and protecting the people of Wisconsin. And then they propose to come along here with a measure which will unbalance that balanced board, and in the hands of any Governor now or one to come may result in the selection of a majority of one particular school of medicine."

(*Continued on page 725—adv. xvii*)

(*Continued from page 724—adv. xvi*)

The lawyer for the Wisconsin Homeopathic Medical Society said that the members of the several schools of treatment were extremely intolerant of one another. He then praised Homeopathy, and said that the President of the United States has a Homeopath for his family doctor, and that the Homeopath's vaccination by swallowing virus was as effective as that done by skin inoculation. He used the old plea of the chiropractors that the people be allowed to employ the practitioner of any system of healing that they choose.

A chiropractor who said he represented 550 of his cult practicing in Wisconsin, exhibited a man with an old vaccination sore healed by chiropractic, and asked the legislators to "stay in the middle of the road and give the people the right to choose whom of the medical profession or those engaged in the healing arts they want."

An Assemblyman said:

"I want to say to this committee that I have had experience with all branches of the healing profession, I presume. I have seen the treatment of the allopaths; I have gone to allopathic doctors; and I have gone to homeopathic doctors; and I have gone to osteopaths; and I have had experience with chiropractors. And I want to say to this committee that I think that all of these branches of the healing art have a very distinct place in our social condition at the present time, and I see no reason for the passage of a bill of this kind. It seems to me that any society which seeks to put this kind of legislation across upon the people of the state of Wisconsin have lost some of their hold on their position in society. And it seems to me that any institution in that society, or any healing art which attempts to say that they should have the controlling force upon any board is weakening their own position, and I wouldn't think that any society would be backing a proposition of this kind."

The bill proposed by the State Medical Society of Wisconsin was defeated.

GRADUATE COURSE IN WISCONSIN

The *Wisconsin Medical Journal* of April contains the following account of a postgraduate course on insulin:

"The University Extension one-day course in insulin and its use is commended to physicians of the State who desire a better acquaintance with this remedial agent and its technique. It is especially recommended to those practitioners who attended medical school before the discovery of insulin; for such physicians, acquaintance with the subject has necessarily been limited.

"The instructional staff includes the following: Leland S. McKittrick, M. D., Boston, Mass., Russell M. Wilder, M. D., University of Chicago, E. L. Sevringhaus, M. D., University of Wiscon-

sin and Lenore L. Healey, Dietitian, University of Wisconsin.

"The sponsors of this course are the State Medical Society of Wisconsin, the University of Wisconsin Medical School, and the University Extension Division.

"The instruction combines an afternoon of lectures and demonstrations for physicians, and a free evening lecture for the lay public. The course is intended to be an inexpensive substitute for a postgraduate course at a metropolitan clinic. In providing for a public evening lecture without cost, in each city, it was thought that, in view of the large number of diabetics who are cared for in the home, there is value in teaching to laymen the necessity of continuous care of these cases under rigid rules prescribed by the family physician. Dr. Sevringhaus' evening lecture for the lay public will stress the avoidance of those diets and fat-reducing methods that have no sound scientific basis.

"A book of instructions for physicians and patients will be given to each physician attending these one-day clinics. It will be found invaluable especially in acquainting the patient with his duties in maintaining the prescribed standards of diet and rules of living. Every item of home equipment and materials for urine testing necessary in the treatment of diabetes will be demonstrated."

GOLF TOURNAMENT IN WEST VIRGINIA

The question of holding a golf tournament in connection with the annual meeting of a State Medical Society has been discussed frequently, with the proponents of the sport gaining ground. THE NEW YORK STATE JOURNAL OF MEDICINE of April 15, page 495, carried an announcement of a proposal to form a golfing association at the next meeting of the State Society. The *West Virginia Medical Journal* of May contains the following editorial on a golf tournament to be held in connection with the annual meeting of the State Society:

"All arrangements for the annual Association golf tournament, which will be played over the course of the Clarksburg Country Club from May 18 to May 20, have been placed with Dr. Frank V. Langfitt, of Clarksburg, and any member-golfers who desire information about the tournament should get in touch with Dr. Langfitt. According

Summer Weather Means Suffering for High Blood Pressure Patients

When the mercury climbs in the thermometer, it is likely to go up in the sphygmomanometer as well. Concentration of the blood resulting from excessive perspiration frequently means higher blood pressure. Symptomatic relief is required.

This relief from physical distress is well afforded by Pulvoids Natrico, which promptly lower blood pressure without shock, pending exact diagnosis and treating of the underlying cause. "One patient I had with a pressure of 300 was lowered to 205 in a week," is representative medical comment on Pulvoids Natrico.

The coupon below, with your check or money order for $5.00, will bring you postpaid a bottle of 1000 Pulvoids Natrico. This is our special price to physicians and hospitals only.

to the precedent established in past years, the tournament will be a handicap affair and each participant will turn in his handicap before entering the tournament. The silver cup will be awarded for the low score after the handicap is deducted.

"The tournament will open at the Clarksburg Country Club on the afternoon of May 18, which is one day before the convention proper gets under way. Play will continue through Tuesday and Wednesday morning. Each participant will play 18 holes and then turn in the score to Dr. Langfitt or his representative at the club. The 18 holes may be played at any time between Monday afternoon and Wednesday noon, but each participant will be required to announce the fact when he begins tournament play.

"The tournament prizes will be awarded at the annual banquet on Wednesday evening. In case of a tie for first place, the tie will be played off on Wednesday afternoon before the banquet takes place. The golf tournament has always been an interesting attraction of the convention and a large number of entrants is expected."

COUNTY SOCIETY ORGANIZATION IN VIRGINIA

The May number of the *Virginia Medical Monthly* contains a letter by the President of the State Society, Dr. J. A. Hodges, who discusses the need of organizing a county medical society in every County of the State. He writes that twelve Counties have not organized societies at all and that ten societies are each composed of from two to nine Counties. Dr. Hodges says in closing:

"It is well known that there are several most efficient group societies with a membership representing physicians from two or more County organizations, and that there are six District Societies composed of more than two (2) Counties which are component units of the State Society, and that there are, also, a number of recognized District Societies, which are not component parts of the State Society. All of these are doing most excellent work, but their activities do not cover the entire field of opportunity. All of these should be continued, and even enlarged, but every County in the State should have at least a skeletal organization, even though some physicians in these Counties may be members of some of the above groups, for, without this, some physicians in each County will be deprived of their privileges and professional opportunities.

"It is most urgent that those physicians who know the value of proper medical organization, should interest themselves in aiding others who are not so fortunate. This will in no sense injure any existing medical organizations, but strengthen them, and give all physicians equal op-

portunities to forward scientific organized medicine. It will also assist the officials of the Society in making practical the new plan of putting into effect the changes in Councilor Districts adopted at the meeting in Norfolk.

"Consequently, the officials of the Society will be pleased to have any assistance, either as individuals, or as members of Society organizations, to aid in this necessary work."

PAY FOR INSURANCE CERTIFICATES IN MICHIGAN

The May number of the Journal of the Michigan State Medical Society carries an editorial describing the official action taken by the officers of the State Society in regard to fees to be charged by doctors for filling out insurance certificates. The writer says:

"During the last three years a persistent effort has been made by the Civic and Industrial Relations Committee to arrive at some definite understanding with the Health and Accident Insurance Companies regarding the payment of a fee of not less than $2.00 for filling out each preliminary and final claim proof.

"Numerous committee meetings, and a conference with representatives of a number of the outstanding insurance companies, have been held and every angle of the situation has been carefully analyzed. The insurance companies strenuously object to the plan and argue that Michigan represents only a small section of the medical profession of the entire United States and are unwilling to concede to the demands of the profession.

"Nevertheless, by its action, Michigan has created the interest and favor of other State medical societies in the question involved. The rights and privileges of the individual physician are being encroached upon by the insurance companies' continual insistence that the filling out of claim blanks is only a part of the physician's professional obligation to his patient.

"This whole question is one which affects every physician in the United States. It affects their income, their time and their convenience. There are approximately 145,000 physicians in the United States. From the statistical standpoint if only one insurance blank were filled out yearly by each physician, it would mean a total sum of $290,000, which the physicians are saving for the insurance companies. Every physician fills out at least ten to twenty of these blanks a year, which means that over a million dollars a year are being contributed to the incomes of the insurance companies. There can be no question that the profession is justified in the stand which they have taken.

"It now becomes quite apparent that the question is one for the consideration of the American Medical Association, and the Michigan delegates are proposing a resolution at the meeting of the Association at Philadelphia in June, which covers this subject from a national viewpoint., Until such action is taken by the American Medical Association as is deemed advisable, the physicians of Michigan are urged to adhere strictly to the import of the resolutions and refuse to fill out blanks for the insurance companies until advance payment of the fee has been arranged."

SOCIALIZATION OF MEDICINE IN ILLINOIS

The socialization of medical services is discussed in the following editorial in the April number of the *Illinois Medical Journal:*

"The lay public, both privately and collectively and from both selfish and altruistic viewpoints, is taking advantage of medicine's contributions. Private citizens and politicians are insisting that medicine be socialized. Life, health, accident and industrial insurance companies are shaping many of their policies on medicine's discoveries. The menace in this respect is manifest in the employment of large numbers of medical men in these industries and in health movements who are being subordinated gradually but surely to a position that is merely that of technicians. Socialization of medicine means the subjection by legislative control and political manipulation, of the medical profession in a system of state medicine which includes any movement which would compel physicians to practice on terms dictated by lay people.

"1. In medical education there is a dangerous trend of the times. Great universities and large foundations, through lay board control, regulate the placement of medical schools, the adoption of curriculums, and dictate the selection and compensation of professors.

"2. A menace in its embryonal stage is the organization of lay institutions which practice medicine. Doctors in these organizations occupy a similar position to employes of life, health, accident and industrial insurance companies, being mere employes who carry out the policies of lay directors.

"3. Another phase of serious and dangerous inherency is the lay influence in the control and management of hospitals. Hospitals are the workshops of the medical profession yet lay trustees outline the policies governing the hospitals. These require visiting physicians often to submit to rules and regulations made by lay superintendents or head nurses, even though these rules and regulations may be contrary to what is considered by physicians as best suited to the welfare of patients.

(Continued on page 731—adv. xxiii)

(*Continued from page 730—adv. xxii*)

"Lay control of hospitals has introduced a new feature into the field of medical practice. Some hospitals are practicing medicine as a business These hospitals are hiring physicians, charging patients for professional advice and treatments by these physicians, collecting the fees and entering them on their books as revenue received By this practice hospitals are actually competing with their staff members. Obviously there are possibilities dangerous to both physicians and hospitals incident to this lay advance into the field of *medical practice.*"

STATE MEDICINE IN NEBRASKA

The May number of the *Nebraska State Medical Journal* has an editorial which is an index of the arguments for and against state medicine It first quotes the A.M.A. definition of state medicine, as follows:

"Any form of treatment, provided, conducted. controlled or subsidized by the federal or any state government, or municipality, except such service as is provided by the Army, Navy, or Public Health Service, and that which is necessary for the control of communicable disease, the treatment of mental disease, the treatment of the indigent sick, and such other services as may be approved by and administered under the direction of or by a local county medical society of which it is a component part.

"It aims to provide adequate medical care for persons not otherwise able to command it. As carried out in a number of European countries all aim to provide a method of distributing the economic load of medical care by requiring a combination of contributions from the insured persons and employers, compulsory savings and indirect taxation. The government administers the fund thus accumulated and employs the physicians. In England for instance it is called the panel system and physicians practicing under the system are called panel physicians. They get about $2,000 per year and are assigned to care for approximately 1,500 persons. All persons whose incomes are less then than 250 pounds a year are compelled to contribute to this fund and are eligible for treatment under the panel system."

The article then lists the arguments for state medicine, as follows:

"1. There is need for improvement of our existing system of medical service.

"2. There is a large amount of unnecessary sickness.

"3. It is the cause and result of much poverty, crime and delinquency.

ETHICS OF READING PAPERS IN MISSISSIPPI

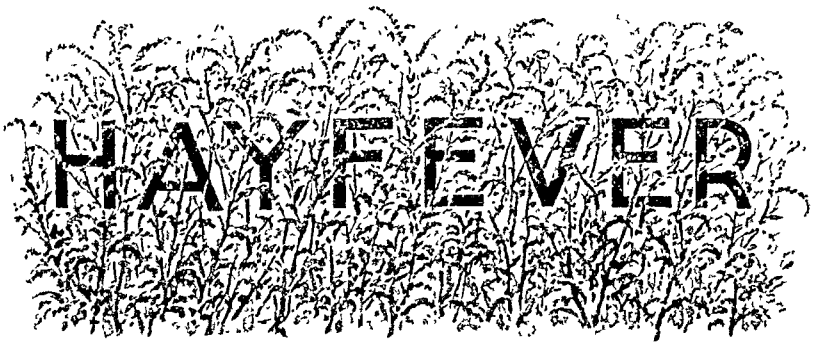
The April number of the *New Orleans Medical and Surgical Journal* contains an editorial by Dr. E. F. Howard, President of the Mississippi State Medical Association, in which he discusses the ethics of reading papers before State Medical Societies, as follows:

"There are two irregularities constantly creeping in that tend to disorder, and sometimes to ill-feeling. One of these is the abominable fault of a paper extending beyond the time limit; the other the extremely discourteous trick of an author, who is unable to attend the meeting, of sending in his paper to be read by someone else

"The law in the matter is entirely clear. 'No address or paper before the Association, except those of the President and Orators, shall occupy more than fifteen minutes in its delivery.' 'Each paper must be read by its author.' These two rules are very frequently over-ridden or disregarded, and invariably it is the fault of the man in the chair.

"A guest failed to come but sent his paper. Someone else read it. The paper ran over the time limit; the chairman called time. Someone moved extension. A protest was raised. Protest was overruled. The By-Law was over-ridden and the paper read to the bitter end.

"Again it was the fault of the Chairman. It was improper to admit the paper; it was equally improper to extend the time limit. Such action is only when done by unanimous consent, which was not possible in either case since a protest had been made. The Chairman should have made a ruling, stuck to his guns and called the next paper.



"There is no use in having laws unless they are obeyed. Far better wipe them all out and let every Chairman run his section to suit himself than have laws that only fetter the law-abiding and are ignored by the others.

"The Secretary prints these rules on a front page of the program every year—and nearly every year one or the other of them is violated.

"All of which is respectfully referred to the attention of the Chairmen and essayists for the 1931 meeting."

GROUP CLINICS, AN OPINION FROM GEORGIA

The March issue of the Journal of the Medical Association of Georgia contains an informative editorial on group clinics, as follows:

"Private Group Clinics"

"A study of private group clinics in the United States, made for the Committee on the Costs of Medical Care, by C. Rufus Rorem, has been issued as Publication No. 8 of the Committee.

"There are approximately 150 such clinics, with a total medical personnel of about 2,000. They represent a comparatively recent development in medical practice, most of those now in existence having been organized since the World War. Almost none is to be found in the Eastern States; the majority are in the middle west.

"The average capital investment in plant and equipment, excluding hospital facilities, was $10,000 per practitioner in seven clinics, which supplied information on this point. The average capital investment in medical equipment and apparatus was $3,600 for 217 practitioners in nineteen clinics supplying information.

"There are two general classes of clinic practitioners: those who share in the ownership of the clinic assets and participate in its profits; those employed solely on a salaried basis. The former group is composed of relatively older men. Data from thirty-four clinics revealed an average of twenty years since graduation from medical school for the 'owners' and eight years since graduation for the 'salaried' physicians.

"Of 415 clinic physicians listed in the 1929 American Medical Directory, 337 were members of the American Medical Association. Clinic physicians were found to belong to specialized associations to a greater extent than independent practitioners in the same communities, a result, in part, of the fact that a larger percentage of clinic members are specialists.

"The distribution of the various specialists among fifty clinics was as follows, indicating those groups in which each specialty was represented by at least one practitioner: internal medicine, fifty; surgery, fifty; eye, ear, nose and throat, forty-six; obstetrics, thirty-seven; urology, thirty-five; pediatrics, thirty; *x*-ray, twenty-seven; pathology, twenty-six; dentistry, seventeen; gynecology, seventeen.

"Perhaps the most striking development in group clinic practice is the 'business office,' a separate department under a lay business manager, who is an employee and whose duties and respon-

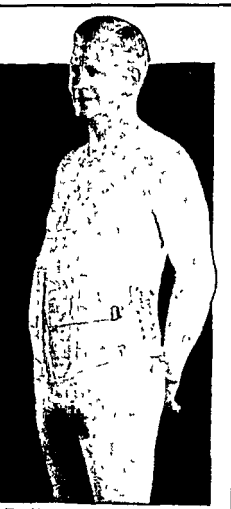
(*Continued on page 735—adv. xxvii*)

sibilities are determined by the clinic physicians. Financial dealings with patients usually rest in the hands of these business managers, physicians wishing, it appears, to have as little of these as possible, although their wishes with regard to the establishment of fees prevail.

"According to statements by forty-two clinic managers, clinic fees appear to be regarded by the general public as neither higher nor lower than those of local doctors in private practice. Twenty-one managers say their fees are 'about the same,' eight say they are 'higher' and thirteen that they are 'lower' than those of independent practitioners.

"The practice of the typical private group clinic is essentially local. The majority of patients, managers say, are persons of moderate means, with a considerable number who might be classed as well-to-do, and a few others who are very poor.

"Approximately one-fourth of 60,000 patients served in fourteen clinics in 1929 were hospitalized during diagnosis or therapy. Approximately 10 per cent of 41,000 patients in ten clinics were treated by major surgery. In twenty-one clinics, 528,000 visits by patients were received by 215 members, an average of 2,459 per practitioner.



"Data were received from twenty-seven clinics regarding gross and net income per practitioner. Gross incomes ranged from $10,708 to $25,606, and net incomes from $5,960 to $17,449. The average gross income for each of the 314 practitioners was $14,908, and the average net income $9,747."

The following conclusions of the Committee are of interest:

"The employment of business managers has usually resulted in increased administrative economy and efficiency. The establishment both of fees and of collection policies is based upon financial data obtained through conventional business methods. Inasmuch as the financial status of a clinic patient is usually investigated, group clinics probably perform less 'free service' than would an equal number of independent practitioners doing the same volume of work.

"Private group clinics, through their available equipment and their coordination of medical specialists, are in a position to fulfill the basic requirements of good medical care with economies from which either or both the clinic members and the public may benefit."

For Abdominal Muscles
that Have Begun to Sag

When, with advancing years, supporting abdominal muscles lose vitality, allowing a sagging of depleted tissue, Camp Supporting Garments bring to the body new vigor and fitness. This model, well adapted for the use of the middle-aged man with long abdominal line, holds the body alert and "at attention", improving appearance and health, gives assuring comfort and overcomes prolapsus tendency. The Camp Patented Adjustment (a feature of all Camp Garments) provides easy manipulation and controls the desired tightness. Constructed of light weight material, this support is especially satisfactory for summer wear. Sold by the better drug and surgical houses.

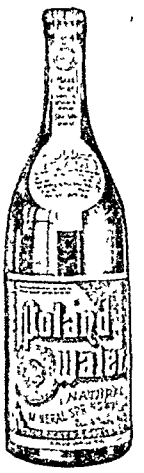
STATE MEDICAL LIBRARIES IN CALIFORNIA

The April number of *California and Western Medicine* describes a legislative bill for establishing medical libraries at state expense:

"The state medical library bill, which was introduced in the present session of the legislature, was briefly presented and discussed on page 803 of the December, 1930, number of *California and Western Medicine*. The bill, as submitted, was a modification of the measure which was introduced two years ago.

"Inasmuch as California maintains at Sacramento a state general library which operates under the jurisdiction of the California Department of Education, it was assumed that the proposed 'state medical library' should naturally find a place under the same department (as a subdivision of the state general library). Because the funds to be expended were public moneys, it was provided that such branches when established should be housed in buildings of the University of California.



"It was found, however, that the California Department of Education was not favorably inclined to taking over the supervision of such a state medical library. It was also learned that a system of divided control was not deemed desirable by the regents of the University of California. The bill was accordingly rewritten so that the state medical libraries should be under the control of the state university, with divisions of approximately equal size in San Francisco and Los Angeles. The libraries would work in close cooperation with existing medical libraries in those cities and would aim to particularly provide 'packet library service' which would promptly, through the mails, bring books and literature on any subject to members of the profession in the northern and southern sections of California. It is hoped that the bill as amended will go on to passage."

LICENSING HEALTH CENTERS IN CALIFORNIA

Licensing health centers and clinics is suggested in the following editorial in the April issue of *California and Western Medicine:*

"A proposed law which has been drafted, but which at the time of this writing has not yet been introduced into the legislature, is one that would demand that every clinic, health center or institution of similar designation or import, which cared for ambulatory patients, would be required to secure a license annually from the California State Board of Health. This bill was prepared by Dr. J. L. Pomeroy, County Health Officer of Los Angeles, and has received the endorsement of the Los Angeles County Board of Supervisors. It was worked over by the Medical Advisory Board of the Los Angeles County Health Department, and was also considered by the proper committees of the California Medical Association. This bill is modeled somewhat after similar laws which have been enacted in the states of Massachusetts and New York. The major object in the measure is to bring about an annual registration of every such clinic or similar institution in California, in order that the public health interests might be properly safeguarded. There was no thought to interfere with the full activities of legitimate clinics, but it was kept in mind that there was great need for some type of inspection and licensure of organizations or institutions which do not measure up to proper standards.

"Members of the California Medical Association will no doubt remember that at the last annual session of the California Medical Association the Committee on Medical Economics, through a special subcommittee brought in a report on the findings which had been gathered in a preliminary survey of clinics and dispensaries in California."

MEDICAL RESPONSIBILITIES

By WILLIAM H. ROSS, M.D., BRENTWOOD, N. Y.

THE PRESIDENT'S ADDRESS AT THE ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, JUNE 2, 1931, IN SYRACUSE

TWO years ago, in accepting office, your President-elect said that he had no illusion as to the size of the task to be assumed when he should fill the office of President; and he has none now. He had no doubt as to the responsibility to be assumed; and it has been greater than he anticipated. He realized that the President should give something of himself to his office. Whether or not your President has done this, you are able to judge. Anyway, he has given all of his time.

Your President has an orientation now, unexpected in the beginning. The problems of medicine are greater than were thought; and their solution is not so easy. The power of tradition is better understood. Any solution involves a change from the customary way of doing things. The physician is conservative because he deals with a multiplicity of uncertain factors. His life is individualistic. He usually applies the same habit of thought to problems of relationships that he applies in directions to a patient. Subconsciously, he thinks of problems in the way that he is accustomed to thinking of the problems of practice. He is not in the habit of having anybody tell him what should be done. Emotional resistance to a substitution of a new proposal for an existing one always appears. The sociological and psychological factor of vested interest influences the acceptance or rejection of an innovation. The minor part of vested interest is economic and the major part is disturbance of prestige and authority.

Medicine is the oldest profession in history. It is older than the civil law. It is the only altruistic profession. It has always determined its own gratuities and contributions to human welfare. It is the only profession intimately associated with the primary instincts of mankind. For ages it has been the only hope of postponing the fear of pain and death. It is, therefore, closely interwoven with the social relations of mankind and inseparably related to the real needs of people. Medicine is, therefore, a social function. It always has been a social function.

The time span of social change has usually been longer than the period of one human life, and during these intervals the profession of medicine developed its traditions. Nowadays something or other is taken into the everyday life of people about every ten years which changes the current of human relationships—the automobile, the radio, the influence of the World War, the present inter-relationship of all the countries of the world, the increasing density of population in cities, the economic depression, and unemployment.

Go with me in thought into one of the European countries and realize that two and one-half million acres devoted to the production of food have in two years been increased to ten million acres with every indication that in two years more it will be increased to twenty-five million acres. This country alone can supply all that the markets of Europe will consume and certain products of America will be reduced to a domestic basis.

The World War changed many consuming countries into producing countries, and has led to world-wide over-production which may well continue. The present unemployment throughout the world may more or less continue. Hospitals and clinics with sufficient endowment may undertake the care of people who have not money to pay for modern treatment; or public opinion may devise an objectionable method of distributing the costs of the hazards of illness. Economic conditions may never again become as they were. Physicians cannot compete with basic economic disturbances any more than industry. Let me repeat that medicine is a social function intimately concerned with the general social condition of people. Whatever affects people economically will affect medicine economically.

Other factors enter into the situation. The public character of medicine and the general knowledge of what can be done to prevent disease

have directed public expectation to the medical profession as the only competent body to develop organization for the administration of the known medical needs today. The profession of medicine is still influenced by the period when a physician was paid by gratuities. The general expectation still exists that under certain circumstances the doctor should give his services.

The world is full of examples of medicine's contribution to the social welfare of mankind. I am not sure that the profession of medicine would like to have this reputation disturbed.

Just as the science of medicine and its application to human ills advance and certain diseases come under control, in the same proportion a physician's work decreases unless he shifts his activity enough to make earlier diagnoses and earlier treatment a part of his work.

There are complexities of society today and enough general economic disturbance to slowly stimulate the state to take on its parental function for the care of the health of its citizens. Since health is an asset to the state and sickness a liability, it is the responsibility of government to take a hand in the solution of health problems not now being taken care of. If the medical profession will recognize that it is the burden of the state to supply certain equipment and certain facilities for the care of its citizens, and that it is the responsibility of the physician to supply the technical service, a partnership will be established which is both in the interest of the public and in the interest of the profession.

If the multitude of indications really show that this nation has reached the peak of its growth, and from now on will more or less approach the social conditions of other countries which caused the government of these countries to take a hand in the solution of relatively similar problems, then the profession of medicine and the leadership of public thought must consider the situation. Medicine cannot be allowed to abandon its historical, social, altruistic, personal relationship to individuals. Some method of rational control of the situation confronting medicine must be thought out.

The importance of health as a basic foundation for every effort in the world—war, industry, stability of government, civilization itself—is accepted by the thoughtful public and illustrated by the interest of governments over the world in health matters. The national study of the costs of medical care and medical service, and the study of child health are but examples.

The total health bill of this country is three per cent of the national income. The physicians of this country receive $750,000,000 per year. There are 120,000 working physicians in this country. They receive $6,250 on the average per year. This is the gross income and out of it they must provide their equipment for practice and transportation. The cost of a medical education today plus the value of the time to acquire it would, if invested at six per cent until the individual is fifty years old, allow him to retire and maintain himself and family for the rest of life without working. The average amount paid for medical service to physicians in this country is $6.25 per capita per year. Hospitals receive about the same amount per capita. The physician is not overpaid. Hospitals are not overpaid. The thinking public is grasping these facts. The general public will sooner or later acquire this information, also. The public, however, knows just about as much concerning this as our own men appear to know and whenever we say that we ought to educate the public as to the problems of medicine, we should add, and our own members also.

The medical profession, accepting certain fixed basic conditions as a guide to its relationships, has gone on quite well until social conditions began to change and complexities of society began to increase. The change from the time when social conditions remained about the same for more than one life time, to the present when they change about every ten years, makes necessary a constant readjustment of medical relationships. The assumption that there is nothing more in medicine than to fill its scientific storehouses, and that each generation of physicians will live amid essentially similar basic conditions as the generation before and the one to come, is for the first time in our history, false.

If there are any who do not yet see that there is a great change in social conditions, let me remind you that it is only about two generations since anyone had a bathtub; that the great increase in hospitals and their use and the phenomenal alvance of the science of medicine are practically all within two decades; that the marvelous educational influence of radio is within one decade and of the automobile within a generation; and the scientists tell us that the ultra-violet light that fascinating agent, is due for a more spectacular sweep into popular use than was expected of radio.

While I do not know that it is possible to work out the future problems of medical relationships except approximately, there is today in medicine an agency that was used in the civic affairs of Greece four thousand years ago. It has been used in industry, in all civic effort, and in the affairs of government. Considered as a medical agency it undertakes to bring opposing interests into conference, to find the common ground, to compromise differences, and to coordinate similar objectives into a cooperative undertaking. It limits waste, increases accomplishment, and defines leadership. We can, at least, find approximate solutions for problems if we adopt enough of the science of foresight.

Walter Brett Donham, in "Business Adrift," says: "The whole structure of the theory and practice of curative medicine on which such outstanding progress is being made is, when applied to the treatment of the individual, subject to just the same hazards as all efforts are to see into the future of medical relationships, and yet we continue to apply it when the individual is sick because useful results are possible."

Since we must accept this method of the application of the science of medicine, it should not be difficult to accept similar reasoning in the relationships of medicine.

Organized medicine assumes responsibilities today unthought of a generation ago,—education, legislation, and others. As a profession, medicine is doing more to meet public criticism today than any other profession. The welfare of future generations of physicians depends upon the correct handling of the problems of today.

Just as there is a world economic disturbance today about which very much is coming to be known, so there is a world disturbance in the relationships of medicine about which much is coming to be known. It involves the economics of medicine as well as the services of medicine. No one alone is big enough to raise an issue, and no one alone can adjust it. It must be a cooperative undertaking. In many respects the problem cannot be met by those untrained in economics. It will require an association with economists and statesmen in the ranks of medicine.

I have lived more or less with these thoughts, ideals, and facts for two years. The principles touched upon in this little address should not be forgotten until the truth is found.

"If you can dream and yet not make dreams your master,
If you can think and not make thoughts your aim,
If you can meet with Triumph and Disaster
And treat these two imposters just the same;
If you can make one heap of all your winnings
And risk it on one turn of 'pitch and toss';
And lose and start again at your beginnings
And never breathe a word about your loss;
If neither foe nor loving friend can hurt you,
If all men count with you, but none too much,
Yours is the Earth and everything that's in it."

ARE THE WIDESPREAD CRITICISMS OF THE MEDICAL PROFESSION JUSTIFIED?

By WILLIAM GERRY MORGAN, M.D., WASHINGTON, D. C., PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION

AN ADDRESS AT THE ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, JUNE 2, 1931, IN SYRACUSE, N. Y.

"O wad some power the giftie gie us
To see oursels as ithers see us."

DURING the past few years there have been appearing an increasing number of published articles, a few by members of our own profession, but a vast majority from the pen of the laity, criticising more or less severely, sometimes harshly, the work of the medical profession, more especially that of the bedside doctor. Occasionally some writer has come to our defense and has ably answered specific criticisms. Criticism for the sake of fault finding, without at the same time offering constructive suggestions, has little creative value.

To attempt to enumerate the more important articles which have been published, condemning in a sweeping manner, the modern practice of medicine, would be impossible in the time at my disposal.

One author makes the trite observation, that "there have been vast changes in medical therapy, both in method and practice since the time of Hippocrates." The physician has been largely the author of the advance in the art and science of healing, and the rank and file have more or less kept up with the progress. He makes the further observation that "medical diagnosis, in spite of modern facilities, is far from infallible, while experts agree that medical education is as a whole entirely inadequate." To this the medical profession can agree. I maintain, however, that this state of affairs exists through no fault of the directing minds of medical progress since medical practice and teaching have been slowly passing through a period of evolution.

Farther along this author states "In the etiquette governing relations among men of the same profession, there are things which savor of a conspiracy against the public," and gives assent to the statement by Ross that "It constitutes a betrayal of the truth, the sick man, and the public." My answer to this criticism is that our code of medical ethics is a bulwark of protection of the public, and in no sense a betrayal of the sick man or the public, because they hold the doctor up to the highest standard of truth, of fair dealing and of giving the best service to the patient and the public, of which he is capable. Another charge is that "Modern medical codes have been somewhat reprocessed, but even tolay

it is very difficult or often impossible for a patient to find out what has been done to him by a surgeon." This appears to me to be a just criticism. In the vast majority of instances, I believe a patient, when he has sufficiently convalesced, has a right to the knowledge of the type and extent of the operation which he has undergone, if he so desires.

Modern specialism in medicine is severely criticized by a prominent medical writer who says "Pseudo-specialism and inefficient specialists are all too prevalent and do much to discredit legitimate specialization." This position is well taken. Many recent graduates in the past and even at the present time are embarking in the practice of specialties having had little or no special training to fit them for their chosen line of work, and too often they have not had the basic training which comes from a period spent in general practice, which is so necessary to the complete understanding of diseases affecting that particular part of the human body which they will be called upon to treat. In the immediate future this trend in medical practice must be corrected if the profession as a whole is to attain the high standard for which we are striving.

Until recent times comparatively few doctors really understood the processes by which the human body is nourished. The subject of food and diet was a "terra incognita," and curiously enough, considered of little importance in the effort to bring relief from bodily ills. Especially was this true of surgeons in their daily work. How often in the early years of my practice have I heard the surgeon, in giving his postoperative orders to the nurse, say "Oh, give him a little toast and tea, or egg albumen,"—an abomination to the man who has had his appendix or gall bladder removed. For this oversight and inattention the surgeons have had to pay very dearly, and their patients much more so. This leads me to call attention to the very just and oft repeated criticism of the profession for the enormous and constantly increasing number of medicaments which are used at the present time by physicians in their daily prescribing. As a matter of fact, do we understand and give sufficient thought to the physiological effects of the medicaments which we administer to our patients? Are we not too prone to be satisfied that this or that drug relieves some specific symptom, heedless of what other effects may accrue to its use? For instance, to relieve an agonizing headache we may administer the old-time antifebrin, heedless of the fact that it may seriously depress the action of the heart and so interfere with the necessary metabolic processes, thus in the end leaving the patient more prone to a recurrence of the symptom from which he seeks relief. A more profound understanding of the action of drugs upon the human body leads the skilled clinician to reduce the number of medicines which he employs as a routine practice. I cannot too strongly emphasize this phase of the practice of medicine. We are too prone and too ready to accept the claims of manufacturers and travelling salesmen as to the virtues of each new group of remedies which are offered to us. This is not a fault confined to the doctor of small experience, but is common to all medical men. When we once fully realize this universal failing, the accruing dividends of pharmaceutical manufacturers will show a progressive downward tendency, to the everlasting benefit of suffering humanity. As Oliver Wendell Holmes said, "If all the medicines in the world were thrown into the sea, it would be better for men and worse for the fishes."

Our medical periodicals in the future must use ever increasing discrimination in advertising remedies for the use of the profession. They must find some other source of revenue from which to draw their financial maintenance. The criticisms which have been so often brought against us in this particular have a just foundation. That the remedy lies entirely in our hands cannot be disputed. The skillful and experienced specialist in any of the fields of practice is less prone to use a wide variety of medicaments than is the average general practitioner.

Another wide-spread oft-repeated criticism of the methods employed by physicians in the treatment of illness is that they use Latin and other unfamiliar terms, both as to medicaments administered and to methods employed, as well as to pathological conditions. It is stated that many druggists have no understanding of the derivation and meaning of many of the terms used upon the prescriptions which they are called upon to fill. This is as true as it is unfortunate. In defense of the use of our terminology I declare that to abandon it would be to open the door to widespread misapplication of many of our medicaments, a large number of which are of high potency for evil as well as for good. In many instances the knowledge by the patient of the particular drug which is being used would inhibit to a certain extent the physiological action of that drug. Then too, there is ever present the danger of creating drug habitues when we are administering narcotics and analgesics. This alone is sufficient justification for our present day method of prescription writing.

Another lay criticism, which has only just recently made its appearance in the press, is that doctors are in the habit of treating symptoms rather than diseases. This is a subject which has of itself been deemed worthy of treatment by physicians in formal and able addresses before medical organizations; and it cannot be discussed in anything like a comprehensive manner in a rambling and discoursive address such as the present one.

No fair-minded individual, be he physician or layman, who understands the treatment of disease

entities, would answer such a criticism in either the affirmative or the negative, and let it go at that. The experienced and conscientious clinician always attempts to make a diagnosis before he undertakes to direct any course of treatment. However, there are instances which occur in every physician's practice where he finds it advisable and necessary to relieve some crippling symptom before he can satisfy himself as to the diagnosis of the disease with which the patient is suffering. Is it not true, nevertheless, that here and there throughout our country there are too many physicians who, because of the enormous pressure under which they are called upon to work, or who taking their obligations to their patients casually, do to some extent prescribe for the relief of the symptoms presented, neglecting the study and observation necessary to determine the underlying cause for these symptoms? In this regard criticism of our methods is somewhat justified. One convincing fact which has been borne in upon me in my travels about the country during the past two years, is that the habit of making snap diagnosis, or no diagnosis at all before instituting treatment is surely giving place, in the routine work of the daily practitioners, to an earnest desire and a determination to study more or less critically every patient coming under his observation. This to my mind is one of the most encouraging signs of the trend of the times in medical circles. As I have so often remarked in the press and from the platform during the past few months, this trend toward more careful study on the part of the bedside doctor in his daily practice is one of the most effective barriers to the adoption of federalized medicine.

The medical profession is held responsible for the lack of some method by which a stranger in a locality would be able to select for himself or his family a competent medical advisor; and further, that the membership of a physician in a county, state, or national association does not guarantee his competency. Can we deny at least the partial truth of such a criticism? Do medical governing boards sufficiently scrutinize, as a routine precautionary measure, the applicants for membership who came before them. Has not the desire for augmented membership sometimes blinded such governing boards to the lack of qualifications of the applicants? What the laity does not realize is the difficulty, at times, of arriving at a conclusion in such matters which is just both to the prospective member and to the public. And how often we are charged with being a close corporation or a self protecting guild when we deny admission to our ranks to those who are unworthy of membership! It may be apropos here to say that the criticisms for the rejection of an applicant usually come largely from the public, whom we are seeking to protect.

Not only have some lay writers, but able experienced clinicians made the statement that physicians do not seek to protect patients from fear of impending disaster, and even at times use this fear as a method for inducing the hesitant individual to undergo some line of treatment which appears to him unnecessary or undesirable for one reason or another. It is undebatable that such criticism has a basis of truth. It seems proper to mention in this connection a matter which is the subject of a wide divergence of opinion, namely, the advisability, in the majority of instances, of acquainting the individual afflicted with some grave malady, as to the true nature of his illness. I take the view that such a course is unwise, except in those cases in which there are grave reasons for doing so. Often such knowledge on the part of the patient proves to be a serious handicap.

Again, as the result of the progress of scientific medicine, new methods and new laboratory tests are being brought out year by year, some to stand the test of clinical practice, and others to have a short vogue only to pass into innocuous desuetude. We are charged with unnecessary application of such methods and tests. I fear there is definite justification for such a criticism. With this criticism, and closely linked thereto, is the one that too often the physician whose duty it is to ultimately evaluate the results of a multiplicity of such tests does not have, or make, the opportunity of coming into sufficient personal contact with the patient to be in a position to give the proper individual interpretation and correlation of the aggregate findings. This inevitably leads to the practice of giving a composite final diagnosis, bewildering alike to the mere bedside doctor and to his patient, to whom such reports are submitted.

Perhaps no other profession is so prone to swing to extremes as is our own medical profession. We are charged with being faddists, a criticism which we find difficult to controvert. If some new line of treatment or an instrument is brought out in Seattle with a sufficient blare of trumpets, in a few days it has travelled with incredible rapidity to Calais, Maine, and on its way has made converts of a large percentage of the medical population in the intervening territory. Were it possible, in the vast majority of instances, to have proven at the outset the undoubted value of such a method or instrument, and to have presented its merits in an understandable manner, the criticism would then be turned to the highest possible praise. However the converse of the proposition is the true one, with the result of the needless expenditure of money and time, and the sad disappointment of the multitude. Every now and then some medical writer complains of the tardiness of the bedside doctor in seeking to learn of and make use of the new and dependable methods which are developed from time to time by the research laboratories or the advanced workers in the field of clinical med-

icine. Concerning this complaint in the practice of the past, we must plead guilty. However, a rapid and decided improvement in this regard is to be noted by the close student of the progress of clinical medicine.

Yet another criticism, voiced largely by some of our leading medical writers, is that we cling too tenaciously to methods which the progress of medical science has found to be valueless. Let us not close our minds to the truth of this observation. I hasten to add, however, that sometimes we are too ready to abandon a drug, an instrument, or a method which has proven of practical value in our hands, in order to adopt some new drug or method which in a short time proves to be only a fad of the moment. It is difficult, having once laid aside something which has been of service to us, to recapture quite the same efficiency in its use as we had originally acquired.

Medical men today are of one mind that specialized practice has reached the limit of practical possibility, and even many students of medical economics believe that we have swung much too far in this direction. In defense of specialization in all lines of human endeavor, I may express in my own words the trite thought that the complexity of life today is such that it is well-nigh impossible for any individual mind to reach perfection in all departments of any profession or industry. Nevertheless, I do feel that society needs, greatly needs, competent, well-grounded, and experienced young practitioners whether it be in medicine, engineering, or trade. The laity is becoming somewhat restive under the wholesale slaughter of teeth and tonsils, so much so that our leading dentists and laryngologists, being held responsible for the failure of relief from some vague symptoms in one part of the body or another, have led the retreat from this, I might almost say, fad. We physicians are now beginning to realize that these appendages are of sufficient value to the human economy to attempt to discover some method by which they may be conserved.

The public openly and repeatedly asserts that the medical profession is lamentably ignorant in the matter of human nutrition. Testimony as to the truth of this criticism is given by some of our foremost internists. There is a slowly developing better understanding of food and food combinations suitable not only for the sick, but for the maintenance of sound health.

Some physicians, and even an occasional lay student of medical economics, call attention to the important fact that our medical teaching, among other shortcomings, fails to give sufficient opportunity to the student for becoming informed as to the reactions of the normal human being to his environment. There can be little doubt that this criticism also has a foundation in fact.

Perhaps the harshest criticism which has yet been voiced by lay writers is that the altruistic aims of the medical profession, upon which is built our pride of tradition, are being rapidly and progressively sacrificed upon the altar of the Golden Calf. Such a charge against our profession ought to be as unjust as it is malicious. Is there, however, just a shade of justification for this indictment? Are we becoming over-commercialized, just a little bit? Maybe, but if so, it is in order to keep pace with the rapidly advancing costs, not only of the practice of medicine, but of maintaining our position in the community in which we live. This impression upon the part of the public is unquestionably gaining ground, and it is the chiefest of the arguments for the adoption of state medicine put forth by its proponents. Because there is perhaps some justification for the criticism that the financial aspect of the practice of medicine has gained a parity with the altruistic aims of the healing art, and because of the importance of this aspect of our professional lives, I feel we have grumbled perhaps a little too persistently about the amount of work which we do for those not in a position to offer us monetary consideration for our services. During the past few months there has come from members of the medical profession here and there, criticism of the plan which I offered in my address to the House of Delegates last year, for a change in the financial arrangement between medical men and the hospitals which they serve. My suggested scheme of renumeration for such service is not inconsistent with my belief that we should be willing to serve without compensation, those members of society who are impoverished. An occasional critic of my method has suggested that it adds force to the advocacy of state medicine. This might be so if at the same time we insisted that the community, county, state, or federal government, pay us in dollars and cents for every item of service which we render to the poor outside of public institutions. I have emphasized this particular phase of our work because, as I have already said, one of our bulwarks against the wide-spread adoption of state medicine is our ready willingness to serve the public to the limit of our capacity regardless of financial reward.

There is an honest conviction in the minds of a good many people that all classes of physicians habitually experiment on their patients in the use of drugs and methods with which they are not sufficiently familiar to make scientific application possible. I dare say that the average physician would indignantly protest that such is not the case. And yet, if we look into this phase of medical practice with an open mind, may we not recognize that there is a basis of truth for the accusation? And further, is there a single member of the profession, in actual practice, who does not do this very thing from time to time? However, the laity is not sufficiently grounded in the science and practice of medicine to dif-

ferentiate between the practice of administering drugs and methods which the physician has not hitherto employed, but with the composition and physiological action of which he is so thoroughly familiar as to warrant his adoption of them; and those physicians who heedlessly and without having familiarized themselves with the composition and physiological action of such remedies, yet prescribes them in the hope that they will hit the target. This is an important distinction.

Another unwholesome practice, which I am thankful to be able to say is gradually passing out, and which has, and is even yet causing unfavorable comment by medical men and the laity, is the practice of fee-splitting. Until comparatively recently the public at large was ignorant of the prevalence of this practice. Within recent months my notice has been attracted by some articles dealing with this subject, in which the stand was taken that if fee-splitting be indulged in aboveboard and with the knowledge and consent of the individual patient concerned, it should be recognized as ethical by medical organizations. Such a position is not well taken, and is a step in the wrong direction. Physicians are human like other members of society, and it would be unwise to place before us a temptation to step just beyond the limits of ethical procedure. The old saying that it is unwise to play with fire lest we get burned, applies somewhat to this question. Personally I should regret the adoption of such an attitude by the profession.

Oft-repeated by laymen is the assertion that our choice of consultants, whether specialist or surgeon, is influenced by some selfish motive, rather than by the skill or competence of the medical man selected. There can be little doubt that this criticism is too often justified. This is a practice which should receive serious thought, since all of us from time to time meet with instances which appear to verify it. We should always consider the best interests of our patients as paramount in the service which we render. And after all, our own best interests and those of our patients are inseparable.

Another cause for dissatisfaction with the service of the physician, voiced constantly by many physicians not in active practice, and also by lay writers, is that we do not discharge our entire obligations to society, in that we hold aloof from community activities outside of our professional routine. For a good many years I have felt the force of this accusation, and have urged on the physicians in my own city the advisability, nay, the vital necessity, as a sacred duty, of becoming active in the civic affairs of our town. There is perhaps some excuse for the reluctance of Washington doctors to interest themselves in civic affairs, because, we are in reality a federally controlled community, without a vote, and with little voice in the conduct of its municipal activities. Nevertheless, we are surely lax in not taking a more active part in the promotion of preventive medicine and social hygiene. It cannot be denied that in many communities the medical profession has been slow to show a disposition to cooperate with the municipal, county, state and federal health services. However, it is encouraging to note everywhere a very marked improvement in the attitude of practicing physicians toward legitimately constituted public health activities.

It is a widely circulated statement by lay writers that the individual of small means cannot exercise his own choice in the selection of his physician. We are reading this criticism so often that it appears advisable to study this question, and should it be found true, to seek a remedy for so regrettable a state of affairs. But after all, is there any real foundation for such a belief? There is little evidence to prove the truth of such an assertion. I wonder just how large or small a proportion of practicing physicians are daily turning from their doors a man or woman because he or she is unable to pay the entire usual fee for the service requested. Methinks the percentage of such physicians would be so small as to be negligible; and certain it is that that type of a physician in the long run would be negligible in his influence upon the standard of the profession; and more than likely he would be derelict in his duty to many patients, regardless of the remuneration he expected to receive. Among the many thousand physicians with whom I have been privileged to come into intimate contact in the United States, Canada, and England during the past two years, I do not believe that there has been one of this type.

An exhaustive survey of the literature, having for its main object criticism of the medical profession coming from the pens of men and women in all walks of life, leaves the student with the definite impression that approximately seventy per cent of such criticisms are without foundation in fact. Of this seventy per cent, some are by conscientious but highly misinformed writers. It is true that as a class we physicians are supersensitive to arraignment of our acts, whether by brother practitioners or by laymen. This is unfortunate, because we should, and we do, learn by our mistakes, which are not brought home sufficiently to our consciousness unless we are held answerable for them. The great Sir William Osler has expressed it succinctly when he said:

"No class of men needs friction so much as physicians; no class gets less. The daily round of the busy practitioner tends to develop an egotism of a most intense kind, to which there is no antidote. The few setbacks are forgotten, the mistakes are often buried, and ten years of successful work tend to make a man touchy, dogmatic, intolerant of correction, and abominably self-centered."

BETTER PRACTICING DOCTORS

By WILLIAM D. JOHNSON, M.D., BATAVIA, N. Y.

THE PRESIDENT'S INAUGURAL ADDRESS AT THE ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, JUNE 2, 1931, IN SYRACUSE, N. Y.

ONE of the most difficult of human problems is the proper evaluation of our immediate surroundings and the relative worth of our activities. We will all subscribe at once to the statement, "There is nothing new under the sun," and in the next breath, hear and tell of some new thing. Nearly everyone thinks the times are out of joint, and his own experiences unique.

Education need not end in doubt, but it stops when a man stops doubting. To sit in the grandstand and watch one's self march by is as impossible as the proverbial lifting of ourselves by our boot-straps, and even the power Burns evoked. "O wad some power the giftie gie us, to see our-

WILLIAM D. JOHNSON, M.D.
President of the Medical Society of the State of New York

sels as ithers see us,"—is generally denied. But for the purposes of demonstration, or argument, some basis of fact must be assured, or allowed, even in a world of relativity, with realization that in its ultimate essence, nothing can be known.

Perhaps Man's distinction among the other animals is that of having created his own environment, mental, physical and moral, so that we, the heirs of all the ages, live in a man-made world "Which one portion would like to make into an Inferno as soon as possible, and the other, with no thought of presumption, into a Paradise at about the same time." We call one portion Devils, the other, Angels.

Evolution still rules the universe, however, and man is but a time phantasm, yet he thinketh himself real. It requires considerable stripping of the haberdashery we have acquired in the past to cancel out the non-essentials and arrive at the basic facts of our being. Healers of the sick, members of the maimed,—these have always been and always will be, "so long as man's body is subject to enmity and casualty." This division of labor did not arise at first from motives of pecuniary gain, but from the cosmic roots of love and self-sacrifice, which in turn had their origin in family life. Then some genius fiend organized the whole thing into a business, and Commercialism, our bane and antidote, was born. That the more ancient of the two motives is that of love and self-respect, is evident by the respect shown it by all, and the scorn in which the mere business man in medicine is held. Sentiment, like habit, becomes firmer with age. That idealism in medicine is the mainspring of what is best and most enduring, is also proven by the type of doctor chosen by young men when they select medicine as a career. I think it could be proven that for one who looks up to the financially successful, there are an hundred whose eyes are turned the other way. If we have established as a premise, "What is of most worth?—What has organized medicine to do about it?"—it would seem that this whole business of ours has been of slow growth without sudden or radical changes at any time. And if History is to be as it always has been, continuous and consistent,—even the events which we call "Revolutions," being only transient and inconsequental in perspective,—the most we can hope for is to hand on to the next relay of torch-bearers an unchanged idealism which, after all, is the only permanent part.

What we call the science of medicine is a most variable and unstable affair, constantly changing and constantly to change. We are justly proud of the body of scientific medicine of today. If we could live into the next generation, we would be ashamed of it. The very ardor with which we defend it shows our suspicion of it. Men fight for their beliefs, not for the things they are sure of.

Are the ideals of our profession in serious danger? I think not,—certainly not from anything within ourselves and only temporarily from with-

out. Kipling says: "Remember always that, except for the appliances we make, the rates at which we move ourselves and our possessions through space, and the words which we use, nothing in life changes." The utmost any generation can do is to rebaptize each spiritual or emotional rebirth in its own tongue. Then it goes to its grave, hot and bothered, because no new birth has been vouchsafed for its salvation or even its relief.

The particular demons we fear in our immediate future may be looked at with equanimity.

State medicine, which a generation or two will try, will fail for several reasons. The main ones are that it will lack the personal one of responsibility and reward, and that an intelligent body of men will not for long lend themselves to the programs of ambitious politicians to buy votes with their free services. That the lay organizations will guide us for long is also unthinkable. Propaganda making under the guise of education in already well understood by the rank and file of our profession, and one has but to turn to St. Paul's first epistle to the Corinthians, Chapter XIII, for a definition of Charity, from which I quote:

"Charity suffereth long and is kind.
Charity envieth not.
Charity vaunteth not itself, is not puffed up;
Doth not behave itself unseemly, seeketh not her own;
Is not easily provoked, thinketh not evil;
Rejoiceth not in iniquity, but rejoiceth in the truth."

The only charity that will endure is the kind that "Blessed him that gives and him that takes." Organized charity is almost a contradiction in terms, and bears the same relation to the real thing that prostitution does to love and marriage.

In the long view our faith in legislation to cure social evils is pathetic. Seventeen thousand new legislative enactments in our country in the last year proves Pope's couplet:

"Hope springs eternal in the human breast,
Man never is, but's always to be blest."

Self-restraint in legislative activities, letting measures "Cure in the wood" might seem wise.

After all, the only way the doctor has got by in the past and will in the future, will be by being the best possible doctor. We would all like the loaves and fishes,—the emoluments and haberdashery of success as the world estimates them, and also to have said over our deathbed the prayer said over the doctor of the old school! "Almighty God, dinna be hard on Weelum McClure, for he was never hard on onybody in Drumtochy,"—but, gentlemen, it can't be done.

"Lord, God of Hosts, be with us yet,
Lest we forget, Lest we forget."

EARLY TREATMENT OF THE CROSS-EYED CHILD

By E. K. HALLOCK, M.D., FREEPORT, N. Y.

In the animal kingdom, any individual who varies markedly from the pattern of his fellows is an object of abuse, derision, and persecution. This is no less true in the human family, and often more so during childhood. A child who is different in body from his fellows may suffer serious psychological harm, in addition to his physical abnormality. His whole adult life may be adversely affected. Among such abnormalities, and impossible to conceal, is the condition of squint, or strabismus.

It has frequently been noted that children with errors of the muscle balance of the eyes are often first brought to the oculist for advice much too late. In many cases, the time has already passed when all of the damage can be undone. The parents are not always at fault. Poor advice is often responsible. The mother is told, and wants very much to believe, that the condition is temporary, and that the child will outgrow it. By the time that she is convinced this is not so, much damage may have been done. Errors of muscle balance lead to serious results, and they should be corrected early in life.

The normal condition of muscle balance is present when, with the gaze fixed on infinity:

1. The eye is in focus, with the ciliary muscle at rest;
2. The axes of the eyes are parallel;
3. With the gaze fixed on nearer objects, the amount of accommodation required is proper for the distance between the object and the eye;
4. The amount of convergence is just sufficient to direct each eye to the object looked at.

Normally, these two functions—accommodation and convergence—are concomitant. For distance, the eyes do not focus actively, and there is no active convergence; for near objects, each eye must focus, and each eye turn in, the proper amount for clear sight. This is binocular fixation; and as a result of it, we acquire binocular single vision—that is, although each eye separately sees the object, still with the two eyes together, only one object is seen. Binocular single vision depends upon the action of the fusion center, the existence of which is inferred. It has not been located anatomically.

The child is not born with an already developed habit of binocular fixation. He learns through experience, by a sort of trial and error method, that vision is clearer when rays of light from the object strike the macula, or most sensitive spot of

the retina. There is at first a pendulum-like oscillation of the eyes, until finally each is brought to rest with the macula in the proper position. Thus binocular fixation is developed as a habit in the earlier months of life. In these first months, therefore, there need be no alarm felt if an occasional deviation is noticed. However, should such deviation last more than a few minutes at a time, advice should be sought; for if binocular fixation does not exist, then single binocular vision is not possible, and the great advantage of stereoscopic sight is lost.

Many faults of muscle balance come from refractive errors, or improper focus of the eye. In such cases, our ideal condition of balance is not present. The amount of focussing effort needed is not proper for the distance between the object and the eye. If the child is far-sighted, he must accommodate for distance, although the normal eye is at rest for distance. But the brain does not realize that the eye is trying to look at a distant object. Because the eye has to focus for a distant object as it should only for an object lying nearby, the brain considers that the object looked at lies nearer to the eye than it really does; and hence the brain converges both eyes to meet at a too-close point, where the object is falsely considered to be located. Now, of course, neither eye is directed at the object; if he is to see it clearly, the child must cause one eye to fix, and let the other eye do all the deviating. His dilemma is this: if each eye is to fix, the object must be out of focus; if the object is to be in focus, it can be seen with only one eye at a time. The child is forced to choose between clear sight with one eye only, or blurred sight with two eyes. The one-eyed sight is always chosen. Usually the better eye is used for fixation, and the other is allowed to deviate. It may then seem that only one eye is crossed, but the condition is essentially binocular, and the angle between the eyes remains the same. In some cases either eye may fix at will; and the condition is then known as an alternating convergence.

If single vision with two eyes depends upon fixation with each eye simultaneously, the reverse is equally true: if a seeing eye deviates, there must be double vision, unless suppression of sight takes place. The sight of the deviating eye is thus a hindrance, not a help. The child would be better off without it. And, too, the more the eye deviates, the better, for the false image is thus moved further away from the true, and the diplopia becomes less annoying. The tendency, then, is always to encourage the eye to cross more and more, and to suppress the vision of the crossing eye more and more. At first, the amount of crossing is greater for near than for distance, as the amount of accommodation is greater; but the child can habituate himself to the condition more easily if the deviation remains constant; and the excessive convergence is encouraged for distance also, and a true convergent strabismus develops. And so the course of events runs: accommodation is needed for distance, when the eye should be in focus while at rest; each eye is forced to turn in, in proportion to the amount of accommodation; the better eye is used for fixation; increased convergence and suppression of sight is encouraged in the deviating eye. Squint, then, is the final outcome of the endeavor to avoid double vision.

As in any other pathological condition, the aim of our treatment must be to remove the cause, and to repair the damage done. The basic factor, the refractive error, can only be corrected by giving the proper glass, after accurate objective measurement of the refraction, which can only be done with the ciliary muscle put at rest by atropin. No other determination of the refractive error is of value, as a large part of it may be covered up by the eye's spasm in its attempt to get clear vision. As the strain on the accommodation is thus removed, the tendency toward excessive convergence is also removed. Still, however, there is a subnormal vision in one eye; unless this is corrected, the better eye will continue to do the most of the work, and the poorer eye will not be used. Here as elsewhere, an atrophy of disuse takes place, and amblyopia results. Also, binocular fixation and fusion are more easily established when the sharpness of sight is about the same in each eye. So by building up, if possible, the sight in the poorer eye, the proper muscle balance is encouraged. This may be done by covering the good eye for a certain period each day; by using a special exercise glass,in which the lens before the good eye is frosted; or by continuing the use of atropin once or twice a week in the good eye. in order to force the other eye into activity. The treatment may be somewhat uncomfortable for a time, but it should be persistent. It should be started early in life, as the chance of material improvement decreases rapidly after the age of six or eight. Our first thought should not be operation to straighten the eyes. It is only when no improvement in sight, or lessening of the convergence has followed the use of the proper glass and orthoptic exercises for at least a year, that operation should be undertaken. It is then indicated, first to make possible binocular single vision, which as we have seen, depends on fixation with the two eyes simultaneously; and second, to relieve the child of the psychological burden which he carries. This is true, even in cases where there is but little hope of any real increase in sight. Operation does not remove the necessity for glasses, as it does not correct the refractive error. If the proper glass is not worn, the convergence frequently recurs after the operation.

Unfortunately, often we do not see these children early enough in life. The mother sometimes tells us just what caused the trouble,—the child had mumps, or it was frightened, or it fell. She

has allowed the condition to go on for several years, sometimes because she has been told the child will outgrow it, and sometimes because she fears she will be told that the child must wear glasses. As a matter of fact, the alleged cause has little to do with the matter. At the most, it merely determines the time of onset of a condition which would occur anyway. The time of a child's life at which he falls out of trees, or has measles or mumps, is about the same time that he begins to call on his eyes for close work, and the focussing strain becomes significant. (The external rectus paralysis which may follow diphtheria is quite another matter. This causes a paralytic squint, which must not be confused with the accommodative type.) As to outgrowing it, this may happen, due to a broadening of the face, but it is a cosmetic cure only, and the eye still remains much subnormal in vision.

The condition in alternating strabismus is somewhat different; glasses alone generally will not suffice. Due to the alternate use, vision is often equal in the two eyes; operation is indicated earlier.

There is also a non-accommodative strabismus, in which the deviation may be the result of, and not the cause of, the poor vision. Hemorrhages at the macula from birth trauma, or other causes, may have reduced sight to such a degree that there is no impulse toward binocular fixation, and so the eye is allowed to deviate. There may even be an actual aversion to binocular fusion, supposedly due to a lack of the normal fusion center. In such cases, the eyes may be in perfect focus, and so nothing can be expected from the use of glasses. Operation is indicated in these children for cosmetic reasons even if the vision is not markedly improved.

ABSCESS OF THE PREGNANT UTERUS; RUPTURE DURING LABOR

By ROBERT LOWELL WOOD, M.D., F.A.C.S., BROOKLYN, N. Y.

MRS. W., aged 30, para one, was first seen on July 27, 1929, at my office, at which time she was six weeks along in her second pregnancy, the last period being on June 11th. She menstruated first at fourteen, every twenty-eighth day, lasting two days only, without pain. She had had a spontaneous dry labor six years ago, the baby weighing eight pounds and twelve ounces, in good condition, and nursed by the mother. A laceration of the perineum had been repaired with good result.

The patient's only illness or indisposition of significance was a pain in her right lower abdomen, which had persisted for five years and which was diagnosed as chronic appendicitis.

Her membranes ruptured spontaneously on February 25, 1930, and she entered the Peck Memorial Hospital, although she had but slight, infrequent pains. On the morning of the 26th, as she was found to be fully dilated, and the head was on the perineum, in the L.O.A. position, with the fetal heart loud and regular, a normal baby was easily delivered with low forceps. The placenta came away spontaneously in ten minutes. Bleeding was slight in amount, and two sutures were placed in the old perineal scar for a tear of the mucous membrane. One ampoule of gynergen was given after the delivery of the placenta, and the patient placed in bed apparently in good condition.

One-half hour after the delivery the patient suddenly began to have agonizing pain in the right lower quadrant. She was pale, her pulse was imperceptible, with blood pressure 60 systolic, her rectal temperature was 99.4 her abdomen was distended and exquisitely tender. A blood count showed 2,100,000 red cells, 10,000 white cells, blood type 2. A blood donor was secured in twenty minutes, and the patient was given 500 cc. of blood by the Scannell method, bringing her pressure up to 110. She was conscious at this time, though 1/6 grain of morphine had been given at her first collapse.

The patient was now transferred to the operating table, and the abdomen opened by a midline incision, when free pus exuded. The appendix and the right tube and ovary were normal, but on the posterior surface of the uterus, just below the right cornu, and behind the round ligament, was a ruptured abscess cavity the size of a walnut, which did not communicate with the cavity of the uterus, as was demonstrated by finger and by probe. Suction drainage of the abdomen was begun, and two Penrose drains were inserted into the cavity and into the cul-de-sac, and the abdomen was partly closed. The patient came down from the operating room conscious, with a slight chill, was cyanotic, and her pulse was of better quality but rapid. Harris rectal instillation of saline was instituted. She was put in Fowler's position, and digifoline 15 minims every four hours, and morphine gr. 1/6 every four hours were given. The patient made a good recovery, and the baby throve on artificial feeding.

The probable diagnosis is that the posterior wall of the uterus had been the site of a small fibroid, which during the time she complained of pain, was undergoing degeneration, with progressive thinning of the wall over it, so that with the first hard contraction it ruptured and produced the shock which nearly caused her death.

PRESENT STATUS OF THE DIAGNOSIS AND TREATMENT OF CANCER*

By WILLIAM P. HEALY, M.D., F.A.C.S., NEW YORK, N. Y.

WHEN one attempts to review any part of the field of medicine, in so far as the developments which have taken place in recent years are concerned, he is almost certain to obtain the impression that during the second half of the nineteenth century the efforts of clinicians and research workers in the medical sciences were devoted largely to the problems of etiology and diagnosis. As a result of these studies especially in bacteriology and pathology, as well as in clinical medicine, our knowledge of the etiologic factors in many of the most serious diseases then prevalent was greatly increased so that when the twentieth century opened it was but natural that the large store of accumulated facts should be turned to a practical purpose.

We find ourselves then in the twentieth century turning this knowledge into weapons for the treatment and prevention of disease. An era of prophylaxis and therapeutics in medicine has been inaugurated which is so successful that, as you will see later, the diseases which caused large numbers of deaths twenty-five and thirty years ago and during the latter part of the nineteenth century such as typhoid fever, tuberculosis, malarial fever and pneumonia have been largely done away with or reduced in frequency as well as mortality.

Our success in combating the contagious and infectious diseases especially from the standpoint of *prevention*, wonderful as it has been, nevertheless has been dimmed by our inability to control two other of the major ills affecting adult life especially. These are heart disease and cancer. Either of these diseases with little or no warning may strike down an apparently healthy adult in the prime of life.

It would seem that Hippocrates (B. C. 460 to 375) was responsible for the use of the term carcinoma as applied to malignant tumors showing progressive growth. Nevertheless the condition now spoken of as cancer was well known and was treated by excision and by caustic ointments a thousand years before the time of Hippocrates. One may then safely say that for thirty-five hundred years or thereabouts the disease known as cancer has been recognized, studied and treated. Throughout the greater part of that time it is true there was much confusion and difference of opinion regarding cancer, its nature and treatment.

Indeed it was only during the past one hundred years and in fact since the construction of the achromatic microscope in 1824 in Paris that the recognition and study of the cellular structure of malignant tumors became possible.

It was through such studies by Waldeyer and his associates that the origin of cancer from epithelial structures was established and the former belief that normal tissues could be transformed into cancer was destroyed. It was also demonstrated that cancer always has a local origin and the metastases or secondary tumors develop from cells arising in the primary tumor and which are then carried elsewhere in the body by the lymph or blood streams.

In this, the twentieth, our own century it is no exaggeration to say that as a result of the great impetus given to the study of cancer both by clinicians and laboratory research workers, as well as statisticians from life insurance companies and lay organizations that the urgent need for an *accurate follow up record over a period of years of* all cases seen and treated in order to determine beyond a reasonable doubt the value of different methods of treatment has been fully recognized and adequately met.

The establishment and maintenance of these follow-up systems has been an added financial burden upon the hospitals that maintain them, but it is felt that the information obtained and the benefit gained for the patients by prompt recognition of unfavorable symptoms often permitting curative measures to be instituted have fully justified the cost.

Moreover the insistence upon unbiased, honest and accurate follow-up records is the best safeguard and, at times, the only reliable check on the quack, the charlatan and the well meaning but mistaken enthusiast who claims or believes that he has a so-called cure for cancer. Such records to be of value must be complete and should consist of the usual clinical history, physical examination, pathologist's report on the microscopic study of the tumor itself or a biopsy specimen removed from the tumor, operation record, treatment chart showing dosage and method of application of radium and *x*-ray if used, or serum, vaccines, foreign proteins, caustic pastes or any other preparation or procedure designed to palliate or cure the disease.

It is only when records of this sort are available for study and review by the profession that the public can be protected from false claims or misguided enthusiasts.

There are few things more pathetic and more deserving of better treatment and protection than the relatives of a patient hopelessly ill with cancer as they reach out in all directions for a miracle to be performed and willingly, with childlike simplicity and confidence, become the prey of quacks. It is on the one hand a tribute to their love and affection for the patient but on the other hand it indicates a complete loss of balanced judgment and intelligent decision on their part.

To the man in the street the term cancer in-

*Read at the meeting of the Medical Society of the County of New York, on December 22, 1930.

dicates a single disease regardless of the organ involved, the histologic structure of the growth or its clinical features. To a certain extent this may also be said of the medical profession as a whole.

On the other hand, those who have had a fair experience in tumor therapy realize that the term cancer includes a vast group of malignant tumors varying greatly in their histologic characteristics, clinical behavior, and response to different forms of therapy, even when these tumors occur in the same organ.

Only a very moderate experience with cancers of the breast for instance will quickly impress one with the marked variation in their gross appearance, rate of growth, spread of metastases, appearance of ulceration and degree of malignancy in different cases and yet to the world at large they are all alike because the term cancer is applied to each. It would be as reasonable to regard all cases of appendicitis as of equal severity and to make no distinction between the mild case and one in which the appendix has ruptured and a severe infectious peritonitis has developed. And yet there is a certain similarity in that the end results in both diseases, cancer and appendicitis, are favorably influenced as you know by early diagnosis and prompt treatment while the disease is still limited to its original site.

One may ask, why is cancer? In other words what is its cause? Despite all that has been done to determine it I regret to say that we are still ignorant of the ultimate cause of cancer.

An important fact for us to realize is that there is absolutely no evidence that cancer is caused by a germ or a parasite. It is therefore not a contagious or an infectious disease and as physicians we know that there is no fear of its being transmitted from one person to another.

Whatever cancer is, it is something that has to do with the life or growth of the body cell. Cancer is regarded as a lawless or wild growth of body cells that has come about as a result of insult to the cell in the way of damage or injury or persistent irritation.

We know that certain organs or parts of the body seem to be predisposed to, or develop cancer more readily than others. When we study those organs in their relationship to the habits or normal activities of the individual we find that in most instances the site at which the disease first appears is one that is more or less subject to irritation or injury.

In the case of lip, tongue and mouth cancers they are prone to be associated with irritation from smoking or from the sharp edges of bad or broken teeth or poorly fitted plates. In the stomach and bowel the location of the growth is always more common at points subject to irritation and injury. Likewise in the uterus, cancer is extremely common in the neck of the womb and we feel that this is, in many instances, a result of neglected lacerations caused by childbirth. Actually about 90 to 95 per cent of all cases of cancer of the neck of the womb occur in women who have borne children. This is far too great a penalty to pay for the great privilege of motherhood and it is the duty and obligation of the medical profession, especially those in general practice and those devoting themselves to obstetrics and gynecology, to see that all lesions of the cervix whether inflammatory or traumatic are promptly treated and cured, to the end that in so far as it is in our power those women, the mothers, may be protected from this disease.

On the other hand this cannot be done without full cooperation on the part of the women themselves and this means regular, annual, periodical, thorough, health examinations.

Because of the extraordinary efforts made in recent years to educate the public regarding the occurrence of cancer and in view of the large sums of money expended by various organizations, in particular the American Society for the Control of Cancer, with the purpose of impressing upon the public the necessity and importance of seeking medical advice promptly in the presence of certain symptoms or conditions suggestive of cancer, and because of the intensive campaigns conducted by county medical societies in the desire to develop a greater interest in periodical medical examinations of all individuals; the question has arisen as to whether or not the medical profession as a whole is prepared to make an early diagnosis of cancer and to institute proper therapy for the lesion when so recognized. Last year Ewing and others, after a careful survey of this question as it affects physicians and the medical service available in this country for the early diagnosis and treatment of cancer, concluded that the medical profession as a whole was not ready to handle the problem.

More recently Wood in a very frank and enlightening review of the question of diagnosis of cancer emphasizes the extreme difficulties which beset the physician in his efforts to make an early and correct diagnosis of cancer.

These difficulties are present not only in the obscure cases of internal cancer which lack clinical symptoms in the early stages and are only recognized as a rule when too far advanced for successful treatment but also in lesions occurring on the surface of the body, in the mouth, the breast and the neck of the womb. In these locations the lesion may be seen and felt and yet the diagnosis in an early stage is often impossible until a portion of the growth has been removed and studied by a tissue pathologist.

On the whole those who tend to criticize physicians for not recognizing cancer in its earliest stages should realize that the disease does not carry a label nor has it any pathognomonic clinical sign or symptom which will permit its recognition in its inception even by the most expert, except

by accident or good fortune, without biopsy and the cooperation of the pathologist.

As a matter of fact many of the patients who present themselves for examination, suffering from a fully established incurable cancer have lost no weight or strength and seem to be otherwise in good health, all of which is confusing and puzzling to the patient's family and friends and sometimes even deceives the physician.

This difficulty in making an exact clinical diagnosis in the earlier stages of the disease does not however excuse the physician from the necessity of making a careful and thorough general physical examination in order to check up the underlying reason for definite symptoms presented by the patient. Unfortunately from time to time patients presenting serious and urgent symptoms see several physicians over a period of weeks or months before they meet with one who makes even a physical examination in an effort to reach a diagnosis. Under such conditions of professional neglect if the patient should be suffering from cancer the chance of effecting a cure is greatly diminished if not entirely lost.

Since it is difficult to make an early diagnosis of cancer at a time when a cure by operation or radiation therapy, either alone or combined, may be expected and as the majority of the cases when seen are suffering from advanced cancer, and a cure by any method is extremely doubtful or improbable, an attitude of pessimism regarding the entire cancer situation has arisen in the minds of both the profession and the public. This attitude we believe is not entirely justified by the facts.

While there is no gainsaying the fact that the earlier the diagnosis the greater the probability of cure regardless of the organ in which the tumor is located, it is nevertheless true since the establishment in recent years of radiation therapy upon a firm foundation that even advanced cases of cancer beyond the reach of surgery or those having recurred after operation have been controlled, made to disappear, and have remained well under irradiation with radium and *x*-ray.

We have come to realize that tumors with certain histological characteristics are radiosensitive and that others with different histological characteristics are radioresistant. In general it may be said that the greater the degree of cellular anaplasia and tendency to lymphatic invasion presented by the tumor the more malignant it will be and the greater will be its radiosensitivity. It will thus be seen that the very conditions which make a bad prognosis in surgery, give a better prognosis when radiation therapy is the method of treatment employed.

This so-called radiosensitivity of tumor tissues is an important and extraordinary reaction. A few weeks ago a lady 60 to 65 years old applied to the Memorial Hospital for treatment, she was found to be suffering from a carcinoma of the vagina which extended from the cervix to the introitus, arose from the anterior vaginal wall and completely blocked the vaginal canal. A diagnosis of cancer too extensive to hope for cure was made. With the thought and intention of doing something to palliate the disease and retard its growth the patient was referred to the roentgen therapy department where she was given what is known as a pelvic cycle consisting of four treatments with the high voltage machine.

To our astonishment in three weeks from the time treatment was started the entire growth had disappeared and six more weeks have now elapsed and there is no indication of its return.

So important do we regard this question of radiosensitivity that the pathologist today makes, in addition to the usual tissue diagnosis as heretofore, an effort to grade the tumor according to the probable degree of radiosensitivity as indicated by the histologic characteristics of the stroma and the cells.

It is rather generally agreed that in the treatment of carcinoma of the cervix radiation therapy has given such satisfactory results both from the standpoint of palliation in advanced cases to five year cures in favorable cases that today hysterectomy is seldom advised for this lesion. This is especially true since the only form of hysterectomy worthy of attempting would be the so-called Wertheim procedure and the operative mortality is so high, 20 to 25 per cent, in the experience of the average surgeon, and the postoperative complications are so distressing that surgeons have very little enthusiasm for the procedure.

The explanation for the satisfactory results following treatment with radium and *x*-ray is due, we believe, to the high degree of radiosensitivity in cervical cancer.

We are learning that to a certain extent radiation therapy may be used to advantage in cancer of the uterine body.

Some of these cases do well with radium alone and others do better if radiation therapy precedes hysterectomy.

These differences are due to variations in radiation sensitivity of the tumor and this in turn depends upon differences in histologic structure. It is thus seen that we tend to become more and more dependent upon the opinion of the tissue pathologist for both the method of treatment and the ultimate prognosis.

From the clinical standpoint it is extremely gratifying to note the increased number of patients referred by their family physicians for opinions on suspicious looking lesions or with symptoms suggestive of beginning carcinoma. From time to time an early cancer is thus recognized but most of the cases fortunately have only what may be termed precancerous lesions. We feel that it is by such watchfulness on the part of the medical profession in clearing up lesions

of the socalled precancerous type that the incidence of cancer can be reduced. Otherwise all the money spent in publicity does nothing to reduce the number of cancer cases or the development of other cases of cancer. It merely tends to prolong the lives of those who already have cancer by encouraging them to seek medical advice sooner and under those conditions a certain number will be cured because of earlier diagnosis.

It is on the other hand extremely important for both the profession and the public to know that cancer, treated early enough is curable. It is no stigma for a patient to develop cancer. Cured cancer patients should be willing to tell the world that they have been cured and thus help to reduce the pessimism that is far too prevalent. There are in this great city today many people who have had cancer and have been cured.

It is on the whole unfortunate that the friends and relatives of cured cancer cases always subsequently conceal the nature of the ailment. The public hears only of the hopeless cases, of those that die, and never a word about those that have been cured.

If I may here sum up briefly some of the thoughts touched upon.

1. An early clinical diagnosis of cancer is largely a speculative matter.

2. Biopsy with microscopic examination of tissue by a competent pathologist is essential for exact diagnosis in the early lesion.

3. To quote W. Sampson Handley—The detection of early cancer is not a one-man job. It may require the cooperation of the patient, the family doctor, the specialist, and the pathologist. It may, in some cases, be impossible even then.

4. If we are to reduce the incidence of cancer, physicians must be on the watch for socalled precancerous conditions as these are usually curable.

5. Much more is being done today to cure and to alleviate cancer than is realized by the profession and the public. Therefore, the usual attitude of pessimism which seems to be associated with the diagnosis of cancer is not altogether justifiable.

6. The responsibility of seeking medical advice promptly for any and all symptoms still rests with the public.

7. The only forms of treatment that have stood the test of time are those dependent upon surgical removal of the lesion with the knife or cautery and treatment with radium and *x-ray*.

THE RELATION OF DIGESTIVE ANOMALIES TO DIGESTIVE NEUROSES*

By JOHN L. KANTOR, M.D., NEW YORK, N. Y.

Introductory

PROPOSITION I. Digestive anomalies explain in part the mechanism of some of the symptoms commonly encountered in functional digestive disorders.

Definitions: A digestive *neurosis* is a disorder of function in the absence of a demonstrable lesion in the end organs of digestion. A *lesion* is an *acquired*, localized alteration of tissue resulting from trauma, infection, vascular disease, neoplasm, or other cause. An *anomaly* is a congenital variation from the usual in the form or structure of an organ.

Digestive Neuroses

In the digestive neuroses the symptoms are assumed to result from disturbances in the nervous control of the digestive function. These disturbances may be classified as follows:

1. A congential generalized autonomic instability or imbalance. This is sometimes described as vagotonia, spasmophilia, or sympathicotonia, depending upon which division of the involuntary nervous system assumes a relative or temporary preponderance. The great mass of neurotics and neurasthenics belong in this group.

2. An acquired generalized autonomic instability. This is probably caused by intoxications which may be either exogenous or endogenous in origin. Among the exogenous nerve poisons are alcohol, nicotin, caffein, lead, narcotics, and possibly vitamin deficiency, in susceptible individuals. Endogenous toxins may be bacterial, endocrine, or metabolic in origin.

3. An acquired localized autonomic instability. Here the related nerve pathways remain "sensitized" after the disappearance of a local organic disorder, an example being a residual post-dysenteric colonic irritability.

4. Reflex digestive disorders resulting from disease in other systems. Syphilis, tuberculosis, nephrolithiasis, and asthma are well-known illustrations.

5. Organic disease of the nervous system. Important nerve centers or pathways may be involved, either directly, by tumors, infections (poliomyelitis) or degenerations (multiple sclerosis), or secondarily, by pressure of inflammatory exudate or scar tissue.

6. Psychasthenia, in which the patient suffers from a disorder of the psychic component of digestion. This means that his symptoms depend on his feelings, moods, or emotions, or else on certain perceptions or ideas if these have, by past

* Read by invitation, before the Binghamton Academy of Medicine, Binghamton, N. Y., January 20, 1931

experience, assumed the form of conditioned reflexes. In this and the next two forms of functional disorders the pathways linking the higher brain centers with the autonomic system have not yet been fully demonstrated by neuroanatomists.

7. The psychoneuroses, chief of which are the anxiety neuroses. The latter develop in sensitive individuals in the face of insoluble personal situations. Other psychoneuroses are nosophobia (fear of disease), melancholia, and hysteria, a striking form of the latter being anorexia nervosa.

8. The psychoses, such as dementia precox, circular mania, and the paranoid states.

The most common symptoms of a functional character as encountered in the practice of gastroenterology are, in the order of their frequency:

Constipation	in 46 per cent. of cases
Flatulence	in 33 per cent. of cases
Vomiting	in 20 per cent. of cases
Headache	in 17 per cent. of cases

Digestive Anomalies

Anomalies represent points of weakness in the body structure. These weak spots predispose the subject to the development of symptoms. Anomalies vary in degree from those incompatible with life to those compatible with life and health except under unusual circumstances.

The symptoms produced by anomalies are extremely variable in their occurrence. The same abnormality may cause symptoms in one subject and not in another; or in the same subject, the symptoms may appear at one time and not at another. The reason for this peculiarity is to be found in the fact that the body as a whole compensates for the presence of a congenital defect. It is only when this compensation breaks that symptoms actually develop. The break in compensation may result from any of the following causes:

1. Mechanical factors. Thus the mere presence of a Meckel's diverticulum causes no discomfort, but if a loop of intestine becomes twisted about the sac, strangulation occurs.

2. Infection. A diverticulum of the colon (partly congenital in origin) is asymptomatic, but if infection is superadded, diverticulitis results.

3. Juxtaposition of two or more anomalies. The combination of a Meckel's diverticulum (primary anomaly) plus contained ectopic gastric mucosa (secondary anomaly) may lead to ulceration, hemorrhage or perforation just as in simple gastric ulcer.

4. Old age and increasing asthenia. This factor is particularly prominent in the case of all hernias and herniations (i.e. diverticula of esophagus, duodenum, colon), in which the weak spots exist from birth but the fully developed condition does not occur until later in life.

5. Associated functional instability. A redundant colon may exist for years without symptoms until a "nervous breakdown" brings out the characteristic rebellious constipation.

These considerations enable us to amplify Proposition I in the following form:

Proposition II. When a neurosis and an anomaly coexist, the former supplies the break in the compensation, the latter furnishes the anatomical mechanism (*anlage*) for the development of symptoms. Or, in other words, the anomaly expresses the specific somatic component of the clinical picture: it grooves the way for the particular symptoms presented.

During the past eight years my associates and I have been studying the anomalies of the digestive tract with particular attention to their clinical significance in a large group of private patients complaining of digestive disorders. Although some of these malformations are relatively rare, others are so common and so intimately associated with the neuroses that we believe them to play a significant role in the practice of every day medicine. From our material, the following illustrations of the above theories are selected for presentation.

Eventration of the Diaphragm

This is a rather rare anomaly—it was found in less than 1 per cent. of over 1800 x-rayed patients. The high position of the diaphragm in these cases is due to diminution or absence of muscular tissue in this organ. The left side is usually affected. The characteristic symptoms, when these are present, are palpitation, precordial or chest distress, belching and flatulence. These are all due to the imprisonment of air in the stomach above the level of the cardia, and in some instances, to imprisoned gas in the distended splenic flexure. As in all cases associated with gas distress the symptoms are not constant but result especially from fatigue, or excessive nervous or emotional strain. The following case is particularly interesting:

A nervous and sensitive young married man was brought to consultation by his wife who objected to his peculiar behavior after meals. As soon as the repast was over he would repeatedly bend over to his left side, accompanying each such gesture with violent efforts at belching. These antics were attributed by his spouse to his neurotic makeup. Fluoroscopic examination quickly revealed the left sided diaphragmatic eventration and proved that the instinctive body bending was in reality a clever device to bring the imprisoned stomach bubble below the level of esophageal entry.

Duodenal Bands

Description. These structures represent the unabsorbed free edge of the lesser omentum. As a result the second portion of the duodenum is pulled over to the right and fixed to the liver, gall bladder or colon. In this way a sharp angulation is produced between the fixed upper and the free

lower portion of the descending duodenum This malformation acts as a point of irritation and is manifested roentgenologically by transient stasis or actual retroperistalsis A low cecum (see below) is associated with these cases twice as often as in the unselected series (36 vs 18%)

Incidence Eighty-five cases of duodenal bands were encountered in 1754 x-rayed subjects, an incidence of almost 5 per cent Women predominated over men in the ratio of 4 to 1, and asthenics over sthenics in the proportion of almost 7 to 1.

Symptoms A definite clinical picture (so called duodenal migraine), seems to be associated with the presence of duodenal bands The characteristic symptoms in the order of their frequency are Nausea (44%), headache (44%), vomiting (41%), frequently of bile, epigastric pain not explained by organic disease (25%), and vertigo (20%). The frequency of each of these symptoms far exceeds its incidence in our control series of 3,000 unselected cases.

Explanation of Symptoms Experimental evidence seems to be unanimous as to the extreme sensitiveness of the duodenum to stimuli It is well known that a short stasis high in the alimentary tube is far more disturbing than a longer block lower down in the canal In the case under discussion the duodenal irritation or stasis may arise from a local mechanism due to pressure of the bands themselves, or from a local plus a remote mechanism in which the bands fix the duodenum and thus render it more susceptible to dragging arising from the following structures

1 A mesenterialized right colon (right coloptosis)
2 A low cecum especially if cecal stasis is present
3 A congenitally short mesentery of the small intestine.
4 Atypical origin of the superior mesenteric artery or its branches

The dragging mentioned above is effective only in the erect posture and is mediated through the following structures which cross the second and third portions of the duodenum

1 The transverse mesocolon
2 The right colic artery
3 The middle colic artery
4 The superior mesenteric artery
5 The root of the mesentery of the small intestine

Such is the probable anatomical substrate in cases of duodenal bands As with other forms of migraine the symptoms are notoriously influenced in their appearance and intensity by the degree of nervous instability manifested by the patient

The Redundant Colon

Description The redundant colon is one that is too long for the individual who owns it The distal colon is usually affected The most common form of redundancy is a long central pelvic loop Other varieties are the "straight efferent loop' and the 'pelvic loop to the right" Although the form of the loop is usually constant in each individual, changes in configuration occasionally occur

For *diagnosis*, both the opaque meal and the opaque enema are essential The former method demonstrates the disturbed physiology, the latter visualizes the actual abnormality in structure The stomach is often displaced to the right and distorted (so called cascade stomach) by the distended loops of redundant colon

Incidence Redundant colons were encountered in 258 of 1614 x-rayed patients, an incidence of 16 per cent Males and females were about equally affected and the distribution as to habitus was also approximately equal, the sthenics predominating but slightly over the asthenics

Symptoms Constipation, the outstanding manifestation of this anomaly, occurred in 69 per cent of cases as compared with a basic incidence of 46 per cent The costiveness is usually, though not invariably, manifested from birth Despite the extreme degree of colonic stasis—a week often intervenes between bowel movements—there is surprisingly little general disturbance as expressed by nausea, vomiting or headaches

Gas distress, present in about the same proportion of cases as is constipation, takes the form of flatulence with localized distention in the left abdomen corresponding precisely to the region of the redundancy Pain is common and is due to spasm and local colitis superimposed on the redundancy It is particularly prominent in those addicted to the use of cathartics and enemas The painful spasms may suggest diverticulitis or cancer of the colon, heart or gall bladder disease or even so called chronic appendicitis

It is important to realize that volvulus can occur only in cases of redundant colon We have the impression that this accident is the direct result of atypical peristalsis produced by violent efforts at purgation

Relation of redundant colon to neuroses The interplay of the functional and structural elements in the production of symptoms is well illustrated by the following instance

The patient was a stocky young mother constipated from childhood Three years ago her constipation became much worse and abdominal pains and gas distention came on Two months ago all her symptoms disappeared completely for six weeks, only to return in full force at the expiration of this period Examination showed a redundant colon, but why this variability in symptoms? Further investigation gave the answer Three years ago the sudden death of her sister furnished the emotional shock for the initial aggravation of her underlying disability Two months ago she skipped a menstrual period and was overjoyed at thinking herself pregnant as she

ardently desired a second baby. When her menses returned after two months' absence her keen disappointment brought on a recurrence of symptoms.

The Low Cecum

Description. This anomaly results from an excess in the normal embryologic process of cecal descent. There is an actual overgrowth of the entire ceco-colon as a result of which the cecum passes beyond its normal point of arrest in the middle of the right iliac fossa and reaches well down into the lower half of the true pelvis. The diagnosis of this anomaly is readily made 9 hours after the administration of a standard opaque meal. Duodenal bands were associated in about eleven per cent. of our cases which is twice their average incidence.

Incidence. The low cecum is the most common anomaly of the digestive tract. It was encountered in 18 per cent. of our cases and occurred two and one-half times more often in women than in men and four times more often in asthenics than in sthenics.

The *symptomatology,* we believe, offers a characteristic clinical picture. Vomiting, which occurs more than twice as often as in unselected cases (43 vs. 20%), is habitual and easy. Attacks are brought on by fatigue, dietary indiscretion, excitement, menstruation, and headache. Vomiting "equivalents" are represented by nausea and car or train sickness, which indeed, often accompany the full-blown symptom. Headaches occur more than one and one-half times as often as in the general series (38 vs. 23%). They are often of the migraine type, may be accompanied by nausea and vomiting, and are either associated with or replaced by vertigo in some cases.

For one reason or another, low cecum patients are frequently operated on for appendicitis. Our records show that this operation has been performed in this particular group more often than in any other we have investigated, actually one and one-half times as often as in the unselected series. On the other hand a "pus" appendix was revealed less often than in any other class of patients. This leads us to conclude that low cecum bearers are often appendicectomized with little apparent justification. This is undoubtedly due to the fact that this condition has been frequently unrecognized and misinterpreted, and that a wrong surgical therapy has been applied for its relief.

Explanation of Symptoms in Low Cecum. Two theories are available. According to the first the cause of the disturbance resides in the cecum. According to the other the symptoms are mediated, surprisingly perhaps, through the duodenum. The evidence seems to be all against the first hypothesis for it is only when cecal stasis occurs in a low cecum that there is increased headache and vomiting. Cecal stasis in normal or high ceca does not seem to produce this result. It follows therefore that the symptoms cannot be due to the cecal stasis as such because if this were the case the stasis should be equally operative no matter where the cecum is located.

According to the duodenal hypothesis the symptoms are the result of intermittent mild duodenal blocks produced by the occasional drag of the distended low cecum, the actual pressure on the duodenum being mediated through the structures which cross its second and third portions as already enumerated. We believe that this theory, though perhaps not completely proven as yet, is strongly supported by embryologic data as well as by the results of surgical observations in cases of advanced chronic duodenal obstruction. Lack of space forbids a detailed presentation of the available evidence but it may be mentioned in passing that in the severe cases the obstruction has actually been relieved by surgical procedures of one sort or another directed to relieve the drag of the offending right colon. It need hardly be added that in the mild cases with which we are here dealing, medical treatment is ordinarily efficacious.

From the foregoing considerations it becomes evident that the syndrome presented by the low cecum is rather complex in its nature. On the anatomical side we have the basic overdescent of the cecum. To this is added a secondary factor, namely cecal or ceco-colic stasis. Now inasmuch as the stasis is essentially the result of colonic malfunction it becomes clear how intimate must be the relation between functional and psychic factors on the one hand, and the anatomical substrate—the anomaly—on the other. This explanation appears all the more reasonable when we recall that the asthenic women who so largely comprise this group are a particularly sensitive and nervously unstable class, all of whose complaints are either initiated or aggravated by strain, fatigue, and emotional excitement.

Summary

1. According to current notions, the symptoms of gastro-intestinal neuroses are attributed entirely to disturbances in the autonomic nervous control of digestion.

2. Stress is laid on the *absence of an acquired lesion* in the end organs of digestion.

3. The possible *coexistence of a congenital digestive anomaly* and its possible role in symptom production is generally overlooked.

4. According to the evidence here presented the neurosis furnishes the underlying functional instability—the break in compensation—and the anomaly, when present, expresses the actual digestive symptomatology of the clinical picture.

MEDICINE AND THE PRESENT SOCIAL TREND

By NELSON KINGSBURY BENTON, M D, NEW YORK, N Y

THIS is a new world, we are told, and we may believe it All about us are the signs of revolution or rapid evolution The world is topsy-turvy and our ideas are in a state of utter confusion Even the children pity their elders for their want of sophistication, and snootily boast the revolt of youth Possibly the early and judicious use of the old fashioned slipper might have done much to curb this revolt

This is the day of criticism, mean, petty and destructive We are to have no heros They have all been dragged from their pedestals, and left sprawling in the mire Washington, Jefferson, Hamilton, Daniel Webster and finally Abraham Lincoln Even the legendary characters of the court of King Arthur or the warriors of ancient Greece, who have, through the ages, represented to childhood certain virtues and desirable qualities, are now reduced to the ridiculous This debunking has just one use, it brings the unknown writer into the light of day and increases his royalties enormously The use of lurid methods for the purpose of attracting attention and gaining a following has become widespread Obscure professors, theologians, child minded senators, ambitious and seemingly sentimental state executives are all seeking places in the sun through criticism of our present institutions and the promise to tear them down And they are succeeding Mob-psychology is doing its work We are all rushing pell-mell, knowing not where we are going nor what we are going to do when we get there And we care little so long as we escape the ignominy of being called conservative

It might be well to pause in our headlong rush, to glance at the band of pipers who are thus leading us like the rats of Hamelin Town We would find very few business men or skilled laborers, a large sprinkling of professional people, especially teachers, and a solid mass of unskilled workers, almost entirely of foreign extraction This last group fills many of our hospital beds, sends its money home to Europe in times of prosperity and in periods of depression sets up such a howl that we are at our wits end to appease it To satisfy the demands of a screeching minority, certain of our legislators are ready to not only rifle the public treasury, but to write into our laws many pages of socialistic doctrine The two programs that now appear most likely to deceive the public and win votes are those that have to do with the provision by the government of power and of health service The groups that have developed these fields to their present high state of efficiency can look for very little consideration at the hands of our manipulators of government When government does enter into competition with private enterprise medicine will be the first to feel the restraint of its cold, dead grasp The picture that presents itself is more drab, if possible, than that of the life of an army medical officer, with his book of army regulations as his principal reference and the writing of reports his chief duty In evidence that this is not pure imagery, there is said to be a bill at this time before the legislature of the Commonwealth of Massachusetts seeking the organization of medicine under State control, along the lines of the army medical corps The only enterprise of any size now operated by the government is the post office This is pointed to by the socialistically and communistically inclined as an example of successful endeavor It is true that we are able to send a letter thousands of miles for two cents, but who will have to make up the deficit for this year amounting to one hundred eighty million dollars? Moreover does anybody know of a more undernourished dejected-looking object than the average postman or postal clerk. And we have no reason for believing that we shall fare better if we permit ourselves to be forced into the employ of the State

Strangely enough, pressure is being brought to bear upon us from most unexpected quarters, by what is popularly known as "big business" and by philanthropies sustained and directed by the owners and leaders of this same big business And the radical among us point with glee at this anomalous situation

The adoption of the Workmen's Compensation Laws suddenly threw an immense burden upon the shoulders of industry To make matters worse, physicians generally shared the attitude of the public, and looked upon the corporations as dragons and monsters to be prodded and jabbed at any opportunity There is of course a limit to the ability of even a corporation to disgorge its seemingly enormous wealth, so they were compelled to enter the businesss of surgery in self protection And at this we cannot complain, for certain qualifications and equipment are needed in industrial surgery as well as a fair stabilization of costs In fact certain industries such as the railroads, steel plants and mines, have had their own surgeons for many years without exciting any unfavorable comment It has become necessary for most companies to require a superficial physical examination of applicants for employment, to discover any defects that might later be attributed to the occupation The examining and much of the surgery must be done by men who are interested in the welfare of the company and who are willing to subscribe to the policy pursued throughout industry of accepting a somewhat lower unit return for quantity production

There seems to be no great objection to this purely industrial portion of their program, but there has been a distinct inclination on the part

of corporations, to extend their efforts to the treatment of sickness not of occupational origin, some going so far as to treat not only their employees but also their families.

A notion of the magnitude of this tendency may be best conveyed by quoting from a paper on the subject "Medicine in Industry from the Standpoint of the Executive," written by the vice-president of a utility company employing twenty-five thousand persons. He says "Right here may I confess that there is financial motive in medical work with us. We do not do it from any eleemosynary sense; we do not carry paternalism quite that far. We are in industrial medicine, if that is what you want to call it, because we think it is profitable to ourselves and to others." Another passage reads "Right here may I say that we share the doubt that exists in general society as to how far industry should go in handling the medical affairs of its employees and we do not do so except in certain emergencies. On the other hand we are inclined to believe that possibly because the State continues to fail adequately to do its entire job in this respect, we may sometime be forced into extending the scope of our medical work." This statement, coming from an executive of an enterprise that is at this very time striving to avoid further government regulation seems strangely to indicate the thought that medicine must be the servant either of the State or of industry. This gives the Golden Rule a somewhat warped appearance.

Among the figures presented by this officer are ten thousand one hundred examinations for employment, four thousand six hundred voluntary examinations, two thousand one hundred X-ray and fluoroscopic examinations, seven thousand six hundred laboratory examinations and the handling of nine thousand cases of minor illness.

A passage in the paper says "Personal consultations with employees and families also numbered about six thousand eight hundred. For instance Johnny Doe, a lineman, who has been with us only a short time, who makes perhaps only thirty-five or forty dollars a week, and who has several children, hasn't much saved and perhaps has no family doctor. He thinks something is wrong with one of his children and he comes to the medical office and says, 'will you look the kid over.' We make it clear that we will be delighted to look the child over, not with any idea of prescribing medicine or treatment, but rather to determine the cause of the derangement and suggesting to the employee a certain form of treatment, that may be provided of course by a physician of his own selection. This is an important element of the work which is tremendously appreciated by the employee." This last statement is true and highly significant, and gives the most probable reason for the continuance and gradual extension of the work. It is the most effective and least expensive way that an employer has, of demonstrating his interest in the employees. And not only the forty dollar man but the one hundred and fifty dollar man is using this service. Nor is the service always a purely advisory one.

From this approximate idea of the work done by a single organization, one may, by multiplying many times, gain some conception of the vast amount of medicine and surgery, entirely beyond the requirements of the compensation act, that has been taken over by industry. This means not only an immense loss in revenue, but a diminishing prestige and an increasing potential danger of being submerged in a system in which we will be mere puppets.

To stay in our little corner sulkily complaining and nourishing a grudge toward the present system will get us nowhere. The concentration of wealth is necessary for the development of our resources and for the distribution of benefits and by taking a forthright attitude we need work neither under nor against industry but with it. To accomplish this we must have a program to offer. Before this can be done our house must be put in order by finding answers to the several problems that now disturb us.

It may be said that our problems resolve themselves into two groups, those of finance and those of ethics. Any equitable solution of the first, however, will render the second group non-existent. Our financial question, like all subjects of dispute, has two aspects; first that seen by the laity who believe that they are being exploited, and second that seen by our members who regard the rewards of service as very unsatisfactory when considered in the light of the large expenditure of time and money in preparation for this service. And it is true that it does involve many years of work and an investment that has recently been estimated at about twenty-eight thousand dollars. But we must not place to much importance on this item for there are many others who spend long years of preparation. Teaching for instance is an outstanding example of a profession offering a very low dividend return. The educational requirements of many vocations are approaching those of medicine.

We are the victims of the same evils that afflict industry; overproduction and unbalanced distribution. The first is being cared for by the sharp reduction in the number of medical schools and the elevation of their requirements. The problem of distribution on the other hand becomes more and more involved. It is of two kinds, first geographic distribution and second distribution among the various departments of the profession. One factor looms large as a cause of this unbalance. This is the lure of specialization which means less work,

greater remuneration and more leisure. The depletion of the country-side is perhaps only proportionate to, and a part of, the general shift of population from rural to urban life that has been under way since the introduction of steam-power and the beginning of the so-called industrial revolution. It is said that the tide is on the turn and that the increasing use and wide availability of electric power is tending to attract industry, and with it population, to the less congested areas. Thus, in the course of many years, may one phase of the difficulty be remedied. In the meantime there remains much to de done.

With most of us trying to be specialists and only about twenty per cent of the patients requiring special attention, it looks as if there would have to be a retreat to the field of general practice; and why not. Slogans and sayings often repeated come to be looked upon as indisputable facts. One of our most rigid fixations is the thought that no one mind can possibly comprehend and use the enormous amount of knowledge that has been brought to bear on the science of medicine. Therefore the field must be divided and redivided until we become as the physicians of Ancient Egypt and each treat a very limited anatomical area and have narrowly defined methods of treatment. It is true that we cannot have a first-hand knowledge of all the chemical and biological studies that are contributing so much to our work. Yet this is no reason why we cannot intelligently use their findings. Unlike the men of former times, we know little of botany and pharmacy. It cannot be said that on this account our use of drugs is inferior to theirs. We cannot read all the medical literature, and it is neither necessary nor desirable that we waste our time doing so. Owing to the insistence by institutions that their members publish papers as well as to the widespread individual desire for publicity, our journals are being packed with quantities of material that has little or no value. Most of us have time or could make time to read the worth-while articles by writers who have a background of experience or research.

Far from being made more complex and difficult by the added knowledge, the practice of medicine should have become more simple and decidedly more interesting. The graduate of twenty years ago, saw little in the practice of internal medicine to inspire him. He had a pharmacopœia full of drugs but had learned that only about seven of them had any value and that he must rely mainly upon the healing power of nature and a good nurse. He quite naturally turned to surgery which offered definite results. Then too there was something spectacular and heroic about surgery and an element of adventure, an attraction not altogether appreciated by the patient. And so we have pushed and crowded into surgery and the surgical specialties until it seems that we must almost outnumber the patients.

The new-type specialist requires no apprenticeship. He just steps out of his internship into a large, well-equipped, luxuriously-furnished office, with nurses and secretaries and other psychological accessories. This has all tended to put surgery on an extremely competitive basis, and has carried the overhead to a level so high, that we suspect that, in observing from these heights, it is difficult to detect the appendix that is not chronic, the tonsil that is not flooding the system with poison, or the pelvic organ that causes no headache.

The inflation is not so much a result of greed as it is a response to popular demand. These recent spendthrift years have brought to the top, great hordes of families, inexperienced and totally unprepared for the affluence that has been poured upon them by the turn of Fortune's Wheel. In the choice of a tailor or of a doctor they have no standard of value other than the dollar. High costs and much display are the outward and visible signs of intrinsic worth. Yet the ever increasing volume of criticism that is being directed at us, has as its principal theme, the excessive cost of medical care. Fee-splitting and unnecessary surgery hold a very secondary place in the complaint of the public. That these evils do exist is undeniable, and they are traceable back to the overcrowding of the specialties. General overproduction is now being largely corrected by the reduction in the number of medical schools. Further efforts at limitation could be accomplished, not so much through higher standards of scholarship, as through greater emphasis on character. Efforts are now in the making for the control of premature specialization through the establishment of special bodies to pass upon the fitness of candidates for particular specialties.

The family physician could again be made the foundation upon which the structure would stand. The crumbs that are now being offered him from the tables of the masters are in no way going to satisfy his appetite. To periodically see his patients and to route them on to others offers no particular thrill. The broad general training given in the schools and hospitals prepares him to carry on fully three quarters of the medical care and to do it in a more satisfactory manner than is possible under the much divided and standardized system toward which we appear to be aiming. The methods of Henry Ford are not applicable to the human economy.

We storm and rage at the rise and spread

of pay clinics and commercial laboratories but make no rational effort to meet the competition. All of this work would go to the so-called ethical laboratory if the fees were anywhere within the same range; but there is a real reason why the rank and file of family physicians are unwilling to spend, for a routine urinalysis for example, more than they ordinarily receive as an office fee. The disproportion is recognized by the patients themselves. Of course, if special consideration is asked it is usually granted, but often grudgingly and in such a manner as to make one feel like a petitioner for alms. All of this becomes more or less irksome and turns the practitioner to those who welcome his patronage. The growth of the clinics may also be largely attributed to the same cause. Innumerable upright, self-respecting citizens, to whom the word charity is altogether distasteful, are compelled to resort to the clinics, in fact many of them are referred there by the family physician because of his inability to bring the necessary investigation within reach of their purses. It could be done and with profit, by some of our own number, who really need the work. But there is an undercurrent of insincerity, false pride and assumed dignity that prevents us from putting our cards on the table and dealing openly with one another.

To many, this discussion of economic questions is uninteresting and almost sordid. They are little affected and find the present situation entirely satisfactory. But, far from being a minor question, of concern to only a small number of unfortunate and dissatisfied doctors, it is an important item in a broad national problem. We must find our own way out of the dilemma and not look to the government for much assistance, or we shall some day find that we have been made the entering wedge for a sweeping system of parentalism. We have seen it occur in one after another of the European Nations, even to Great Britain, the stronghold of conservatism. Let us not have too great a feeling of security. The most glaring example, of the ability of an earnest minority to suddenly impose its will upon us, was the adoption of the Eighteenth Amendment. We are approaching a fork in the road where we shall be called upon to decide whether we are to turn to the left toward the Russian Experiment, or to go straight ahead, carrying to its utmost state of perfection, our own American Experiment.

This is a capitalist nation. The hateful, envious and malicious accuse us of it. We admit it and have no reason for being ashamed of it. Therefore instead of trying to combine elements of two systems, that mix no better than oil and water, let us, in solving the problems of medicine, follow the usage of a benign capitalism, and adopt the principle of co-operation by agreement.

A striking example of the success of this method is furnished by the recent satisfactory arrangement arrived at between the Economic Committee and the insurance carriers, the latter conceding the right of the patient to choose his physician from among the members of the County Society, while the companies are to be given the support of the society in seeking a fair adjustment of costs.

That our organization and its officers are wide awake and fully aware of the need of political and economic thought and action is undoubted. Their most difficult task is to jostle the rest of us out of our state of inertia.

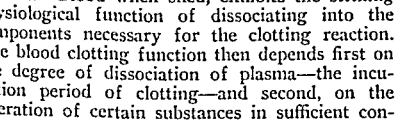
Among several laudable projects under way or in the making, the move for a central registry for dispensary patients promises to be the most immediately helpful. It will not only prevent misuse of the dispensary privilege and end reduplication of effort, but it may even be hoped that it will make unnecessary the maintenance of out-patient departments by some of the hospitals so that they can devote their efforts to the ward services. Patients requiring free treatment could be directed to the teaching clinics where they are needed for demonstration purposes. The teaching institutions could then discontinue their pay-clinics and the foundations would find an outlet for their funds through contributing to the support of these school clinics. This would centralize research and place it in the hands of the more competent.

Other suggested undertakings are bureaus for the collection of delinquent accounts, for credit rating and even an insurance organization and a finance corporation so that the public could pay for its health service as it does for other things; on the partial payment plan. All of these would seem to merit serious consideration. But they should be undertaken, not as independent medical enterprises, but in conjunction with existing commercial agencies having an unimpeachable reputation and a nationwide scope. Just as we resent the intrusion of corporations in our field, so should we avoid trespassing on their territory.

With these agencies in operation, it is conceivable that a system of rating for patients could be developed, based upon income and number of dependents. This could be arrived at through a frank questioning of the patient and confirmed, if necessary, by consulting the credit-rating bureau. A standard card could be devised to be filled in by the family physician for each of his patients, giving the rating and his own fee in the particular case. In addition the card might carry all facts that would

be useful to the collection bureau in case of necessity. When referring the patient for special investigation or treatment, a copy of this card would be mailed to the consultant who could then base his fee on the rating of the patient and on the fee of the family physician. If this became the universal practice, the public could in no way resent what might otherwise be looked upon as idle curiosity.

For all these reactionary jottings, one might easily be sent to Siberia. After all, any hope that we may have of arriving at a satisfactory settlement of our difficulties, depends upon unity of purpose and action. There may be some necessity for militant efforts. Some will say that we must not act like a labor union. But let us not be smothered by our own dignity; let us not be too proud to fight.



THE DETERMINATION OF BLOOD CLOTTING FUNCTION

By I. NEWTON KUGELMASS, M.D., NEW YORK, N. Y.

From the Department of Pediatric Research, Fifth Avenue Hospital, New York.

HEMORRHAGIC disorders manifested by the tendency to bleed or to clot are first recognized either by symptom or by routine clotting and bleeding time determinations. The clinical diagnosis of hemorrhagic problems is thus based on active expression of a disordered clotting function. An attempt has been made to recognize the early manifestations of potential bleeding or clotting tendencies. The clotting time determination of occasional significance in frank bleeding problems may nevertheless be normal though spontaneous bleeding be present or may be delayed though there be no hemorrhage. It is this paucity of procedure for the evaluation of the presence of a bleeding or clotting problem that simple methods have been developed for the determination of each of the individual factors involved in the clotting process.[1]

Physico-chemical studies reveal that blood plasma, so long as its constituents are not dissociated by extraneous forces, is a single complex in equilibrium, rather than a mixture of substances. Blood when shed, exhibits the striking physiological function of dissociating into the components necessary for the clotting reaction. The blood clotting function then depends first on the degree of dissociation of plasma—the incubation period of clotting—and second, on the liberation of certain substances in sufficient concentration to form a gel—the actual clotting. The dissociation of shed blood adequate to yield a clot is a determining pre-clot function. A graphic presentation of this process would be as follows:

The quantitative determination of the dissociated compounds involved in blood coagulation offers a basis for evaluating the clotting function of blood. And the value of each of the clotting substances of a patient gives us an insight into the nature of the clotting deficiency and hence the hemorrhagic status of the child. All of the determinations given below may be carried out in an hour.

1. *The Value of the Clotting Time:* The blood-clotting time is essential, but not conclusive for determining the hemorrhagic tendency of a patient. The clotting time may be normal though spontaneous bleeding be present, i.e., in purpura and jaundice, and clotting may be delayed although there be no hemorrhage.

The determination of the clotting time of blood passing through skin is no criterion of the true clotting status of blood and hence no indication of what might be expected in the operative field of other tissues. All injured tissues, as well as blood when shed, dissociate into substances conducive to their coagulation. This contributory tissue factor may be eliminated by taking the clotting time by vein puncture.

Clotting Time (Vein Puncture): Draw one cubic centimetre of blood, transfer to a test-tube eight millemetres in diameter (the greater the diameter of the tube, the slower the clotting). Place the tube in a water-bath at 38°. Coagulation is complete when the tube can be inverted without displacing the clot. (Normal, five to eight minutes.)

Clotting Time (Skin Puncture): Touch the end of a capillary tube (3 cm. x 0.6 mm.) to the first drop of blood issuing from a stab in the finger or ear. Place in the creases of the palm and cover by closing the hand to maintain a fairly uniform temperature (34°-35° C.). The clot initiation time (latent period) is the first visible departure from fluidity. The clot formation time is the first fibrin thread seen between the ends when the capillary is broken by bits every half minute. (Normal, three to five minutes.)

2. *Properties of Antithrombin:* Antithrombin is the substance maintaining the stability of the

plasma complex. When blood is shed the dissociation of the plasma produces clotting components which, by mass action, decrease the stabilizing effect of the antithrombin. Its content is directly proportional to the colloid stability of the blood. High antithrombin values indicate a hemorrhagic tendency and low values indicate accentuated coagulability of blood.

Antithrombin Index:[2] Blood obtained by skin puncture is drawn into a Wright tube, allowed to clot and then centrifuged, 0.1 cubic centimetre serum is drawn off into a small test-tube by means of a capillary pipette and heated in a water-bath at 60° C. for ten minutes. (Prothrombin is thus destroyed.) A control blood is carried through the same procedure. The heated serums are cooled and to each is added 0.3 cubic centimetre prepared thrombin solution. The tubes are placed in a water-bath at 38° C. The antithrombin index is the ratio of the clotting time of the patient's blood to that of the control.

TABLE I.

Antithrombin Test

Heated Serum	Thrombin	Fibrogen	Clotting time at 38°	
c.c.	c.c.	c.c.	Control	Patient
0.1	0.3	0.5	5 minutes	x

Incubation time, 15 minutes

Preparation of Fibrogen: Blood from the slaughterhouse is drawn into a vessel containing sufficient sodium citrate to give a final concentration of 0.5 per cent. The plasma is collected by centrifugation and to each twenty-five cubic centimetres are added four grams of sodium chloride. The precipitate fibrogen is collected, washed several times in 15 per cent sodium chloride containing 0.5 per cent sodium citrate.

Preparation of Thrombin: Twenty-five cubic centimetres of the plasma, collected by the above procedure, are precipitated by ten grams of ammonium sulphate and filtered by means of a Buchner suction funnel. The ammonium sulphate is expressed as completely as possible to obviate the necessity for dialysis. The precipitate containing the plasma prothrombin may be preserved for weeks as a moist paste. The thrombin solution is prepared by dissolving 0.25 grams of the paste in ten cubic centimetres of water, adding two cubic centimetres of a one per cent solution of $CaCl_26H_2O$. This thrombin solution remains active for several hours.

3. *Properties of Prothrombin.*[3]: Prothrombin is a protein substance identified with albumin and globulin and is electro-negative in blood. It acts as a nucleus of electrical condensation of the clotting components in the formation of a gel. Its concentration is directly proportional to the clotting activity of blood. High values indicate accentuated coagulation of blood and low values indicate a tendency to bleeding.

Prothrombin Index: Blood obtained by skin puncture is drawn into a Wright tube containing 0.1 cubic centimetre of 1 per cent sodium oxalate and centrifuged. One-tenth cubic centimetre of the plasma is placed in three tubes (6.8 x 1.3 c.m., flat bottom) in a water-bath at 38°C. and to these are added in series 0.1, 0.2 and 0.3 cubic centimetres of 0.5 per cent calcium chloride. The shortest clotting time in the series is the prothrombin time. The prothrombin index is the ratio of the clotting of the control to that of the patient's blood.

TABLE II.

Prothrombin Test

Oxalated Plasma C.C.	0.5 per cent $CaCl_2$ c.c.	Clotting time at 38° Control 3 minutes	Patient x
0.1	0.1		
0.1	0.2		
0.1	0.3		

4. *Properties of Fibrinogen:* Fibrinogen of body fluids is a globulin formed in the liver and coagulable by thrombin. It constitutes the potential clot structure dispersed in the plasma in the most readily precipitable form. Its transformation into soluble fibrin completes the clotting reaction. High fibrinogen content accelerates clotting and synaeresis or retraction of the firm fibrin clot from the gel. Low fibrinogen content gives a non-resistant skein inadequate for retraction in arresting hemorrhage.

Fibrinogen Value[4]: Blood is drawn into a tube containing 0.2 cubic centimetres of 3.5 per cent sodium citrate and centrifuged under albolene. The refractive index of one drop of the plasma at 38° is estimated by means of a Pulfirish Refractometer. One-tenth cubic centimetre of 1.5 per cent $CaCl_26H_2O$ is added to the tube to coagulate the fibrinogen, and is then centrifuged. The refractive index of a drop of the serum is then determined. The percentage of the blood fibrinogen is the difference between the indices of plasma and serum multiplied by the factor 0.187.

5. *Properties of Platelets:* Platelets are lipoidal protoplasmic separations from megakaryocytes in the bone marrow. They are protein-phosopholipin complexes containing 70 per cent protein, 15 per cent lipoids, 5 per cent cholesterol and 5 per cent basic salts. Clotting of blood takes place, other factors being equal, when there is an adequate platelet content and a rapid platelet disintegration, liberating phosphatides. In fact, platelets which do not agglutinate rapidly are functionless for clotting.

Platelet Count: Draw blood with a red blood count pipette and dilute with a 3 per cent citrate (1.200) without adding any stain as a dilutent. Allow the cell to stand for ten minutes before counting the platelets in the customary counting chamber.

Platelet Lysis Percentage[5]: Blood is collected into a short paraffined tube and platelet counts are made at fifteen-minute intervals, counting

TABLE III

Blood Analysis of Clotting Components (Normal Values)

Name	Diagnosis	Clotting Time	Bleeding Time	Prothrombin	Fibrinogen Per cent	Antithrombin	Platelets	Platelet disintegration Per cent	Clotting Index

only those which are single and not agglutinated into clumps The platelet lysis percentage is the fraction of the platelets which disintegrates within one hour

Calculation of the Index of Blood Clotting Function Normal blood shows on analysis that the clotting components are contained in fairly constant concentrations Typical normal values are given as representative of determinations made on patients with normal blood clotting function

The constancy of the values in blood clotting functions is evident from the above data on some of the patients studied as controls The variation in platelets is within the accepted normal range We have come to believe that high platelet counts are associated with chronic infection The rate of platelet disintegration at the end of one hour is over 40 per cent, the low normal level

A composite value of the ability of a blood to clot may be calculated from these determinations Certain of the blood substances, i e , prothrombin, fibrinogen and platelets tend to favor clotting, and other (antithrombin) tend to reverse this process, i e , favor bleeding In this chemical mechanism the activity for clotting or bleeding is proportional to the concentration of each interactive substance

$$\frac{\text{Prothrombin} + \text{Platelets}}{\text{Fibrinogen}} + \frac{}{\text{Antithrombin}}$$

Expressing this reaction in terms of the law of mass action we have

$$\frac{(\text{Prothrombin}) \times (\text{Fibrinogen}) \times (\text{Platelets})}{(\text{Antithrombin})} = 1$$

Introducing normal values for these substances,

Prothrombin Index	= 1
Fibrinogen	= 0 5 per cent
Platelets	= 200 000
Platelets Lysis	= 50 per cent in 1 hr
Active Platelets	= 100,000
Antithrombin Index	= 1 0

The normal index of clotting function of blood is therefore, 0 5 ± 0 2 Values over 1 0 indicate a marked tendency to clot and values below 0 2 indicate a marked tendency to bleed

The clotting function index has been a more accurate clinical criterion of the condition of the patient than has hitherto been available by laboratory methods In certain chronic diseases, however, in which the platelets have been markedly increased, no direct relation has been observed between the unusually high clotting index and the possibly increased blood coagulability We have therefore evaluated the clotting function from the limiting factors

$$I = \frac{(\text{Prothrombin}) \times (\text{Fibrinogen})}{\text{Antithrombin}}$$

The normal index thus becomes 0 5 ± 0 2

FIVE YEARS AFTER

A Résumé of the Remote Effects of the Treatment of Hay Fever and Asthma with High Frequency Electricity.

By WILLIAM GRANT LEWI, M.D., NEW YORK, N. Y.

IN the June 1st, 1926, issue of THE NEW YORK STATE JOURNAL OF MEDICINE there was included a paper on Hay Fever and Asthma that I had read the previous March before the Medical Society of the County of Albany. This paper embodied the method employed and results of treatment in 132 of these cases treated with high frequency electricity at the General Electric Plant at Schenectady during the season of 1925.

Our records at the end of the season disclosed that:

25	of	these	patients	had	improved	from	90 to	100%
33	"	"	"	"	"	"	70 to	80%
28	"	"	"	"	"	"	50 to	60%
27	"	"	"	"	"	"	25 to	40%
6	"	"	"	"	"	under	25%	
12 had shown no improvement								

I am presenting this in the belief that those who read that article at the time of its publication will be interested to know the remote effects of the method of treatment described therein.

In drawing my "Conclusions" I said: "From experience of the past we shall expect that the cases that were benefited last season (1925) will maintain that improvement during the coming and subsequent years: and that a large proportion of those who were not benefited last year (1925) will show improvement during the coming season (1926).

It is, as a rule, hazardous to make medical predictions: but this one has proved prophetic!

In the fall of 1926 questionnaires were sent to all of these patients asking as to their condition during the season of 1926 as compared with 1925 and previous years. Inasmuch as the personnel in an industrial plant like the G. E. is ever shifting, we were very much gratified to receive 82 replies, 65% of the total. We feel that the results reported by this percentage may be taken as an indication of the results of the entire group.

(A) Thirty-five (35) reported that their condition had been better in 1926 than in 1925. These had all improved under treatment the previous year.

(B) Five (5) who had shown no improvement in 1925, the year they had been treated, reported that their hay fever had been much better the following season:—in 1926.

(C) Twenty (20) who had shown improvement in 1925 reported a maintenance of the same condition of improvement during the season of 1926.

(D) Twenty-one (21) who had shown improvement in 1925 reported that their condition in 1926 was not as good as it had been the previous year under treatment.

6 reported attacks milder than in years prior to 1925, but not as mild as in 1925.

12 reported attacks just the same as prior to 1925.

3 reported attacks more severe than in previous years.

(E) One (1) who had shown no improvement in 1925 reported the same condition of unimprovement during 1926.

An analysis of these replies shows that:

50% (A and B) were better as to their hay fever during the season following treatment *(1926) than they were during the season* they had been treated (1925), indicating in A, a still more normal condition of the structures involved—a continued improvement—: and, in B, a remote effect on these structures that was not manifest at the time of treatment.

25% (C) maintained the improvement manifest during the season they were treated:—1925.

25% (D) failed to maintain the improvement manifest during the season they were treated and the symptoms recurred.

One case (E) failed to show any improvement, either near or remote.

Having in mind the remote effects of this treatment, and especially in those cases where there had been no amelioration of symptoms during the time of treatment in both hay fever and asthma, I recall the case of a professional man of standing and intelligence whom I treated in 1927 and whose hay fever was *not* improved under treatment. The following winter he joined a relatively new religious cult:—and has had no hay fever since. He, and his fellow neoreligionists, attribute his relief to his having adopted the new cult. In the light of many such cases, I believe it is due to the remote effects of the treatment he received in 1927.

I would not elaborate on the foregoing if it were an isolated instance: but it is a very usual occurrence to learn of a case that had not improved during the season of being treated but who the next season finds himself free of all symptoms: and who attributes his relief to something he has done, or taken; perhaps deep breathing; perhaps bicarbonate of soda; perhaps joining a new cult; but always something that has never been known to relieve hay fever, but the latest thing the patient tried.

In order to learn of the more remote effects of this single season's treatment, administered in 1925, letters were sent to all of these patients in the fall of 1930, inquiring regarding their condition as to hay fever and coincidental asthma during the intervening years. Due to changes of

addresses and other causes more than half of these letters were returned as undeliverable.

Twelve replies were eventually received, less than ten per cent. But the reports were so overwhelmingly uniform that they are deemed worthy of recording.

Six report entire freedom from hay fever—and asthma where that symptom was present—since 1925.

Four report attacks of little consequence, lasting but two or three days.

Two report that they still have hay fever but "much better" and "less troubled each year."

History and details of the cases where the patients answered the letter of 1930:

Case 1, Mrs. L. D.—Hay fever and asthma for 20 years or more. Some symptoms, especially asthma, all year, but worse in summer. Age, 55.

Symptoms: Sneezing, cough, itching of eyes, headache, asthma.

Treated in 1925 from July 18 to Sept. 15. 19 treatments.

Improvement in 1925; 100%.

Letter of 1926: No hay fever or asthma since taking treatment in 1925.

Letter of 1930: "I have not had the Hay Fever or Asthma since your treatment in 1925."

Case 19, J. P. O.—Hay fever for ten years. Age, 35.

Symptoms: Sneezing, itching of eyes, running of eyes and nose.

Treated in 1925 from Aug. 14 to Sept. 28. 16 treatments.

Improvement in 1925: 90%.

Letter of 1926: Hay fever not as good as in 1925: not as bad as in previous years.

Letter of 1930: "I am happy to say I am greatly improved. Had no return of it with the exception of one or two days."

Case 57, G. E. F.—Hay fever for 12 years. Age, 50.

Symptoms: Sneezing, cough, itching of eyes and ears, headache.

Treated in 1925 from July 28 to Sept. 25. 23 treatments.

Improvement in 1925: 75%.

Letter of 1926: "Had none this year."

Letter of 1930: "Have been free from hay fever since 1925."

Case 61, L. N. M.—Hay fever for 7 years. Age, 28.

Symptoms: Sneezing, some cough, itching of eyes and of ears, running of eyes and ears, general weakness.

Treated in 1925 from Aug. 22 to Sept. 28. 16 treatments.

Improvement in 1925: 60%.

Letter of 1926: "Practically no trace this year."

Letter of 1930: "Treatment was very beneficial the first year; had a trace the next year, although it did not affect me in any way as it did previously. Last summer was not bothered appreciably and have had none this year."

Case 66, E. S.—Hay fever for 15 years. Age, 37.

Symptoms: Sneezing, cough itching of eyes, asthma.

Treated in 1925 from July 20 to Aug. 31. 19 treatments.

Improvement in 1925: Little improvement of general symptoms: Improvement of asthma, 60%. Rated as 60% improved.

Letter of 1926: "Hay fever about the same as last year. Not as bad as in former years. No asthma up to time of writing."

Letter of 1930: "Am waiting to see if my hay fever will return, but it has not although the other boys are sneezing nicely."

Case 68, R. V. G.—Hay fever for 17 years. Age, 35.

Symptoms: Sneezing, itching of eyes and ears, asthma.

Treated in 1925 from July 30 to Aug. 31. 11 treatments.

Improvement in 1925: 50%.

Letter of 1926: "Much better than in 1925. Asthma also much better."

Letter of 1930: "My hay fever has been with me every year since (1925) but in what I feel a more moderate form. Early in 1929 I moved to Philadelphia (from Schenectady) and during the summers of 1929 and 1930 I felt that my hay fever was not nearly as bad as in former years."

Case 88, F. A. H.—Hay fever for 49 years. (Since infancy.) Age, 49.

Symptoms: Sneezing, itching of eyes and of ears, headache.

Treated in 1925 from July 22 to Sept. 1. 11 treatments.

Improvement in 1925: 50%.

Letter of 1926: "Not as severe or annoying as last year. Decidedly milder than in previous years."

Letter of 1930: "I am delighted that for the past three or four years I have been comparatively free from my old enemy. Although I am NOT entirely free from it, I have suffered so very little from it, that I have regarded the mild attacks as a mere matter of fact."

Case 90, J. C. W.—Hay fever for 20 years. Age, 29.

Symptoms: Sneezing, itching of eyes, a light asthma.

Treated in 1925 from July 22 to Sept. 30. 18 treatments.

Improvement in 1925: 40%.

Letter of 1926: "Slightly better than last year and previous years."

Letter of 1930: "I am not having much trouble from hay fever except when I go south or west."

Case 105, D. K.—Hay fever for 27 years. (Since infancy.) Age, 27.
Symptoms: Sneezing, itching of eyes, asthma.
Treated in 1925 from Aug. 25 to Sept. 28. 14 treatments.
Improvement in 1925: 25%.
Letter of 1926: "Better than last year."
Letter of 1930: "Outside of a cold in the head at different times I am O.K. Pleased to say no more from hay fever."

Case 114, W. C. W.—Hay fever for 29 years. Age, 35.
Symptoms: Sneezing, cough, itching of eyes, a little asthma.
Treated in 1925 from July 18 to Sept. 28. 21 treatments.
Improvement in 1925: 25%.
Letter of 1926: "About the same as last year: possibly a little worse. Difficult to compare with previous years as condition has been so variable."
Letter of 1930: "It is my impression that on the average I am less troubled with hay fever each year."

Case 49, I. M. D.—Hay fever for 19 years. Age, 49.
Symptoms: Sneezing, itching of eyes and ears.
Treated in 1925 from July 23 to Sept. 19. 17 treatments.
Improvement in 1925: 75%.
No reply in 1926.
Letter of 1930: "Was disturbed only three or four days this season. Has been of short duration since 1925."

Case 81, J. W.—Hay fever for 5 years. Age, 43.
Symptoms: Sneezing, cough, running and itching of eyes and ears, asthma.
Treated in 1925 from Aug. 1 to Aug. 25. 10 treatments.
Improvement in 1925: 50%.
No reply in 1926.
Letter of 1930: "Slight cold at times in the summer, but no more hay fever, bad cough or asthma."

As far as I have been able to learn, in no case where asthma had been present as part of the seasonal attack prior to 1925, has there been a return of that symptom.

In my paper of 1926, previously referred to, it is mentioned that careful records were kept of all of these cases. These records, with the replies to the questionnaires of 1925 and 1930, are still available for examination.

In administering this treatment I employ a type of high frequency apparatus that is not in general use:—that is, in fact, obsolete: but it is a fact that with no other type of apparatus as yet devised can a current be developed that will produce favorable results in these conditions. I make this statement with the authority of experience. I have repeatedly and persistently treated cases of hay fever and asthma with other types of high frequency apparatus; but have failed to get favorable results excepting with the old type. Experts in electro-therapeutic measures have used this method of treatment with other, more modern, types of apparatus and have failed to get favorable results, as they have told me. Some of them forthwith condemned the method as of no avail. This is just what might have been expected. If we wanted to use diathermy, or do cutting operations, or fulguration, or desiccation, we would procure the apparatus that develops a current adaptable to the particular procedure, or we should. There are many kinds of high frequency apparatuses and currents. And if it is desired to treat bronchial asthma and kindred conditions with high frequency electricity the proper apparatus, that develops the proper current, should be employed. The technique is simple, as has been fully described: but—the procedure must be carried out with the indicated apparatus, otherwise the results will be negligible.

Inasmuch as the apparatus I use develops a current of over 3,300,000 cycles I have been tempted to designate it as *higher* frequency electricity.

I want to take this occasion to repeat and emphasize what I have said before, in private and in open meeting, namely, my willingness to demonstrate, at any asthma clinic in New York City, the comparative values of this method of treatment and the treatment regularly employed at such clinic.

I am ready to install an apparatus at no expense to clinic or hospital: to attend regularly: to divide a group of fifty or more patients with asthma, or hay fever, or both, into two equal groups: the clinic to treat one-half by its method or methods: I to treat the other half by my method: and compare results: in the cases of hay fever, as the season advances: in cases of bronchial asthma, at the expiration of four months' treatment.

I am still hopeful that this proffer may be accepted by one of the large clinics of the City and that the physicians of that clinic, and any others who are interested, may be in a position to judge of the effectiveness of this method of treatment in relieving, and in most cases permanently relieving, bronchial asthma, hay fever and kindred conditions.

PUPILLARY REACTIONS IN HEALTH AND IN DISEASES OTHER THAN OCULAR

By W. H. HOLZAPFEL, M.D., NEW YORK, N. Y.

THIS subject covers many volumes, but for the sake of brevity I will confine my remarks to reactions caused by other than ocular diseases.

The behavior of the pupils in health and disease affords a valuable and interesting study to any one who understands the impulses controlling the phenomena of pupil contraction, expansion and rigidity. If the pupil reacts normally, it does not necessarily mean that the patient possesses good health, but if the pupils do NOT react normally, we are sure of some abnormality, either in the eye itself or in the nervous or vascular system.

Let us consider briefly the anatomy of the parts with which we are dealing. The iris is the anterior segment of the tunica vasculosa, composed of structures partly ectodermal and partly mesodermal in origin, and affords valuable data open to naked eye inspection in cases of diseased states and congenital abnormalities of other parts of the tunica vasculosa which are concealed from direct unaided inspection (the ciliary body and choroid), and also in states referable to the nervous coat of the eye (the retina).

The iris has sensory and motor nerves, and for the sake of avoiding confusion, I will limit my remarks to the motor nerves.

The ciliary branch of the motor oculi supplies the circular or contracting fibres, and the sympathetic supplies the radiating or dilator fibres.

To work out the various pathways of the afferent and efferent fibres, and the various arcs, would be like attempting to unravel the meshwork of a multiplicity of diagrammatic cobwebs.

My purpose is to give a few helpful points in diagnosis rather than attempt to cover the field.

Budge's Ciliospinal Center. This name has been given to the neuronic collection of cells that constitute the origin of the pupil-dilating fibres. It is situated in the cord between the exits of the fourth dorsal and sixth cervical nerves. Stimulation of the cilio spinal center or any part of the sympathetic system will cause dilation of the pupil, while paralysis of the sympathetic system will inhibit dilation.

Motor Oculi. If the ciliary branches of the motor oculi going to the circular fibres are stimulated, the pupil will contract; if paralyzed, the pupil will NOT contract.

Light Reflexes. To trace light reflexes, we must keep in mind the paths through which the impulses travel. Microscopic examination of the optic nerve reveals coarse and fine bundles of nerve fibres. The coarse bundles contain the pupillo-motor fibres, while the fine bundles contain the visual fibres.

The pupillary light reflex arc consists of a system of nerve fibres which have their origin in the retina, and traverse the optic nerve along with the visual fibres, semi-decussating in the chiasm, and ending in the pupil center, viz: the anterior corpus quadrigeminum, and from this, connecting neurons give off other neurons which enter the third nerve, passing thence to the ciliary ganglion in the orbit finally reaching the sphincter pupillae.

Width of Pupil. In health, the width of the pupil varies with age. In the new-born infant the pupils are very small, due to the fact that the sensorium still slumbers. The new-born infant cannot see until its nervous system has developed sufficiently to receive and convey impressions. During youth pupils are frequently very large, due to developed sympathetic nerves and elasticity of iris tissue. During adult life, the pupil again becomes smaller, due to a gradual loss of elasticity in the iris tissue.

The Dilated Pupil in Disease. There are three types, viz:—

Dilated and responsive.
Dilated and sluggish.
Dilated and fixed.

The dilated and responsive pupil is found in cases of cortical blindness, as from bilateral hemorrhage in the visual areas in the cuneus. Advanced sinuisitis with scotoma. Reflex from intestinal disorders in infants and children through spinal irritation. Catalepsy and acute mania. Rare central tumors of the brain, and in certain cases of effusion in the brain meninges or the ventricles.

The dilated and sluggish pupil is found in many cases of paresis in which we often notice inequality of pupils (anisocoria). Also in many cases of cerebral syphilis and basilar meningitis. Also in tuberculous meningitis, and epidemic cerebro-spinal meningitis.

The dilated and fixed pupil is found in cases of third nerve paralysis, usually in one eye, cerebral neoplasm, abscess, cyst, meningitis, internal hydrocephalus. Any pressure sufficient to paralyze the nuclear center controlling the sphincter pupillae, any condition in or near the orbit that will stretch the optic nerve, such as bulging of the orbital wall of the ethmoid sinus,—occasionally seen following scarlet fever. A tumor or cyst of the hypophysis pressing on the chiasm. Transitory cerebral states, as syncope, epilepsy, transitory irritation of the spinal cord from convulsions due to teething or intestinal fermentation.

We should keep clearly in mind that paralysis

of the sympathetic nerve will cause the pupil to contract to pinpoint, and paralysis of the brain will cause widely dilated and fixed pupils, while stimulation of the spinal cord will cause dilation, and stimulation of the brain will cause contraction of the pupils.

In general anaesthesia we must decide whether the sudden dilation of the pupils is due to spinal irritation from gastric disturbance, or paralysis of the brain.

In suspected poisoning we must decide whether the contracted pupil is due to opium or uremic poisoning. We must note the "Hippus" or bounding pupil in hysteria, chorea or mania; the widely dilated pupils due to brain pressure or brain abscess; the dilated pupil on one side in hemorrhage in one hemisphere of the brain, the Argyll-Robertson pupil of spinal syphilis; the unequal deformed and more or less fixed pupils in general paresis or cerebral syphilis, and normal pupils in sham fits.

Let us differentiate between the small pupil in uremic poisoning, and the small pupil in morphine poisoning. In uremia, the poisons within the brain produce irritation to the contracting centers causing a spastic contraction of the circular fibres of the iris, and strong light thrown into the eye cannot produce further contraction, because the circular fibres of the iris are already stimulated to their utmost by the irritations of poisons in the brain. A dilated pupil due to alcohol poisoning will not contract because there is no vision. However, a dilated pupil in the last stages of uremia will react to light because there is vision.

Morphine poisoning. The pupil in morphine poisoning is similar to the pupil in uremic poisoning, very small, the contraction being due to paralysis of the sympathetic, which in turn, permits relaxation of the radiating or dilating fibres, thereby permitting the circular or contracting fibres to function without resistance. The differential point to stress is the contracted pupil in morphine poisoning can be made to contract still further under strong illumination, whereas in uremic poisoning, the extreme intracranial irritation has caused a spastic contraction upon which illumination will have no effect.

Coma from increased cerebral pressure will cause dilation of the pupils due to pressure paralysis of the nerves controlling the circular or contracting fibres of the iris, while uremic coma causes contracted pupils that will not respond to illumination. However, just before death, in uremic coma, the pupils, relax, indicating paralysis of the brain and oncoming death.

Argyll-Robertson pupils, or reflex iridoplegia, is a condition in which both the direct and indirect reactions of the pupil to light are lost, but reflex contraction remains intact which is brought about by the associated actions of accommodation for near vision and the convergence of the visual axes. If the accommodation-convergence reflex arc is not intact, there will be no further contraction.

Reflex iridoplegia is most frequently associated with tabes, but is occasionally found in cases of multiple sclerosis, railway spine, and congenital feeble-mindedness.

Although the presence of Argyll-Robertson pupil declares for syphilis in the majority of cases, yet it is conceivable that a person possessing symmetrical lesions which disorganize the cilio spinal centers, or non syphilitic symmetrical lesions of the pupil-dilating centers in the medulla near the floor of the fourth ventricle, could present typical Argyll-Robertson pupils.

Dilated pupils. In subconscious states, as mesmerism, hypnotism, somnambulism, etc., the pupils are dilated and fixed. However, the opposite is true in normal unconsciousness (sleep), viz: pupils are small.

Traumatic neurosis and medico legal cases. In true traumatic neurosis, the pupils are rarely found to be affected. Occasionally a mydriatic is used in one eye for the purpose of fraud. However, the use of eserine will assist in making the diagnosis. "Hippus," if present, in a case of Traumatic Neurosis would assist in establishing the patient's claim for damages, for "Hippus" is to be regarded as being due to an unstable nervous system or prolonged shock.

Rabies. Not infrequently the family physician is asked if a pet dog has rabies, and if you find a pinhole contraction of the pupils, you are safe in making a diagnosis of rabies. This peculiar symptom does not occur in other diseases common among cats, dogs and rabbits.

Before closing, let us consider unilateral pneumonia. Statistics reveal that 75 per cent of these cases show a dilated pupil on the affected side. The explanation remains a question.

After all is said and done, we must remember two fundamental principles, viz: That irritation of a nerve will stimulate, and paralysis will retard its action. It will be well to remember also that pupillary reactions in diseases other than ocular, are not pathognomonic, but simply a link in the chain of evidence.

NEW YORK STATE JOURNAL OF MEDICINE

Published semi monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication.

For list of officers of County Medical Societies, see this issue, advertising page XXVI

THE NEW ADMINISTRATION

This issue marks the transition of the Medical Society of the State of New York from one administration to another. The list of officers for the coming year appears on the upper part of this page, but the changes are so few that a casual reader might not notice them Only a very few officers and chairmen have retired from active service, but some have been promoted to broader duties; while those who appear on the list for the first time have won recognition by their excellent work in their District Branches and County Societies

The administration affairs of the Medical Society of the State of New York are conducted by men whose wisdom and experience have been demonstrated in actual service

REPORTERS OF COUNTY SOCIETY NEWS

The New York State Journal of Medicine is maintained for the purpose of recording the activities of the Medical Society of the State of New York and its component organizations—the eight District Branches and the sixty County Societies. It is the natural source from which information regarding these sixty-nine societies may be obtained. The official minutes of each society are not generally available for general reference, for only a copy or two are made; but the Journal makes twelve thousand copies available.

The House of Delegates, on June first, considered methods of obtaining more complete reports, especially from the County Societies; and voted to suggest to each County Society that it appoint a reporter, who may be either the secretary or any other member interested in medical reporting. Each Society is therefore expected to appoint a reporter who shall supply items for the news section of the Journal.

Every periodical has its standards regarding the substance of the articles which it publishes, and the methods of forwarding the items. *The New York State Journal of Medicine* conforms to the following standards regarding its medical news items:

1. They shall be of permanent value, as distinguished from the ephemeral and merely personal.

2. They shall be of interest to physicians and public health workers throughout the State.

3. They shall represent the action and opinions of the Society, rather than those of individual physicians.

There will naturally be wide variations in the interpretation of these standards by the reporters of the sixty-nine societies from whom news items are expected. All items will therefore be subject to editorial action; but this action is always collective as distinguished from that of one managing editor. The staff which conducts the Journal is organized on the most democratic basis possible, and the chain of authority and responsibility is as follows:

1. The Executive Editor, employed on a full-time basis to attend to the details of editorial work, publication, and printing.

2. The Editor-in-Chief, whose duties are largely supervisory.

3. The Publication Committee, whose duties are similar to those of a board of directors.

4. The Executive Committee of the Council, which is charged by the By-Laws of the State Society with the duty of superintending all publications of the Society.

5. The Council.

6. The House of Delegates.

All news items, except those of a routine nature, are submitted to the Editor-in-Chief, who is in almost daily contact with the editorial office. Many items are also referred to members of the Publication Committee, who must often give decisions and authorizations promptly by telephone. Frequently, too, items are referred to the Executive Committee, which meets monthly.

In addition to all this, every account of an important conference, or committee meeting reported by the editorial staff is submitted to the presiding officer or chairman of the acting committee for his approval. Every effort is therefore put forth to make the news items truly representative of the policies of the Medical Society of the State of New York.

Bearing these principles in mind, how shall the reporter or secretary send the news of his County Society? The editors appreciate a report in a form ready for the printer; but the important thing is to *send the news*. The items come in all sorts of shapes—beautifully typed, roughly scrawled, or clipped from newspapers. The Executive Editor will put the items in proper shape, no matter in what form they are received.

Only fifty per cent of the counties have heretofore sent news items. Let us make that percentage one hundred, through the appointment of a reporter in every county.

THE NEW YORK STATE DIETETIC ASSOCIATION

The modern service of medicine is given not only by physicians but also by groups of workers in allied fields of science. The first group to be affiliated with physicians was that of nurses, and then the laboratory technicians. Psychologists and welfare workers were next added. Physical trainers also entered the field with so much publicity that the popular idea of keeping fit is that it depends on muscular exercise. Finally there has sprung up a new group, the dieticians, who have only recently organized as a separate entity with the probability of acquiring the dignity of a profession.

The New York State Dietetic Association was organized in Rochester on May 24, 1930, by representatives from six cities. It now has 110 members, and is rapidly developing an important sphere of influence. It has branch associations in several parts of the State, and is itself a branch of the American Dietetic

Association It held its second meeting in Syracuse on Tuesday and Wednesday, June 2 and 3, of this year, at which a representative of the Medical Society of the State of New York was present by invitation The program began with a luncheon, and after dinner speaking. There were papers on diet in different diseases, and a moving picture on 'Standards of Tray and Dining Room Service' There were also social teas and trips to several institutions Altogether the program was one of sociability and recreation as well as instruction

The officers elected at the Syracuse meeting were as follows

President Blanche Bohach, Rochester General Hospital

Vice-President Virginia Howard Ray, Albany Hospital

Secretary Anne Padget, Crouse Irving Hospital, Syracuse

Treasurer Ursula Senn, Buffalo City Hospital

There is a definite field for the New York State Dietetic Association in evolving standards for the practice of dietetics At present a dietician may be a glorified cook, or a saleslady for the manufacture of food A dietician is in fact a cook who may be expected to make food tasty and attractive with regard for the individuality of those whom she serves Every dietician should be compelled to eat the food which she prepares

But a dietician has her own troubles with doctors who prescribe diets as they would pills They are also in frequent conflict with hospital managers who do not permit the dieticians to come in contact with patients Food is the first thing which a patient talks about on leaving a hospital If the dietician who makes up the trays came into contact with the patients, she would adapt the food to their tastes and add immeasurably to the prestige and reputation of the hospital

The Dietetic Association also has a place in the field of popular health education where talks and writings are often conventionalized People get tired of being told that they must eat a leafy vegetable every day and drink a quart of milk, and that every child must take his spinach whether he likes it or not There is more to the subject of diet than such statements as "Lettuce is good for you" To practice dietetics successfully, one must have the broad knowledge of human nature and a sympathy that would do credit to a doctor

The physicians of New York State approve the aspirations of the Dietetic Association, and wish its members success in developing methods of feeding both the sick and the well

---

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Modern Medical Practice This Journal of June, 1906, contains the following editorial comments on some of the modern conceptions of diseases and their treatment, which are still applicable in these modern days

"The saddest spectacle in all the practice of medicine is that of the doctor dealing out medicine to a patient who does not need it, but who does need to be told how to live

"The practice of medicine has not yet been cured of its drug addiction Do you remember what your professor of materia medica and therapeutics taught you outside of the products of the drug store? Very little The best things in our therapeutic armamentarium he scarcely mentioned Fresh air, the bath, food, proper clothing, proper breathing, exercise, proper eating, sleep, rest as a therapeutic agent, the curative power of work, the care of the mind, the training of the child,—how little really well formulated knowledge we have of these most vital things compared with our well formulated knowledge of the uses of drugs The charlatan steps in and masters one of these subjects and scores many a triumph over the doctor of medicine

"I have seen a man dying with pneumonia in a room so close that the nurse had a perpetual headache, but the poor man was taking oxygen from the drug store Why? Because the use of oxygen from the drug store was taught by the professor of materia medica and therapeutics, but not the use of the oxygen of the free and open air which can be secured without the mystic scroll which means recipe

"Dr Treves has emphasized the beneficence of diseases, and he has gone so far as to allege that we should all have been dead long ago had it not been for diseases What Dr Treves refers to is that the symptoms of disease, the suffering of disease are but a manifestation of an effort on the part of the body to throw off some offending and harmful foreign substance Whether it is ptomains or cucumbers that are causing the trouble, the symptoms are but an evidence of a salutary effort of the organism to rid itself of the noxious invader This we know full well to be true Peritonitis has saved more lives than all the drowsy syrups of the East"

MEDICAL PROGRESS

The Hypoglycemic Symptom Complex.—In the opinion of Reinwein hypoglycemic symptoms in diabetic patients are easily overcome provided they are correctly diagnosed. This author has observed that a diabetic coma is much oftener assumed erroneously than a hypoglycemia. Incorrect diagnoses are unfortunately due to the fact that the physician forgets to examine a catheter specimen of urine, and the further fact that the hypoglycemic state is not very familiar to most physicians. There is also an erroneous idea prevalent that hypoglycemia begins with convulsions. As a matter of fact these are seldom seen in experimental hypoglycemia in animals. Three illustrative cases show impressively that if injection of glucose does not at once restore the patient this does not militate against the assumption of hypoglycemia. Animals of course awake very quickly after small doses of glucose, but one must also reflect that the amount of metabolism is also much smaller. In most cases intravenous glucose acts promptly, but a uniform relation between hypoglycemia—as presented in the lowering of blood sugar and in the clinical symptoms—and the amount of glucose injected is difficult to draw up, since we do not know the content of the tissues in blood sugar. If all these points are borne in mind, the recognition and treatment of hypoglycemic symptoms are not difficult, provided further that the physician remains consistent in his therapeutic management and does not shift back to insulin in a panic over a possible mistaken diagnosis. It is still too little understood that in these attacks the psychic behavior is changed, and may in fact be the chief symptom of the threatening or actual hypoglycemia. In one case cited a man on a well-established diabetic regimen was seized with diarrhea which by interfering with resorption of food upset the relation between insulin and diet, and led to violent delirium from hypoglycemia. By dividing the insulin dosage and changing the diet the patient was restored. The patient must be made to understand clearly that insulin treatment will be successful only under properly tested conditions, and that any tampering with the prearranged insulin dosage is dangerous.—*Deutsche medizinische Wochenschrift*, April 3, 1931.

The Mode of Action of Intravenous Injections of Glucose.—W. S. Collens, M. Goldzieher, and H. Koster describe in the *Klinische Wochenschrift* of March 28, 1931, the studies in which they engaged with a view to determining (1) the fate of intravenously injected sugar in the body, and (2) whether objectively demonstrable changes exist which can be attributed to the favorable action of sugar. In the belief that glucose injected intravenously is readily accepted by the body as fuel and that its presence is revealed by changes in the respiratory quotient, they carried out a series of tests in patients who were about to undergo abdominal operations for various conditions, all of whom had been fasting for 14 to 18 hours. After determination of the respiratory quotient, each patient received an intravenous injection of 250 c.c. of a 20 per cent glucose solution. Determinations of the respiratory quotient were made again 30 minutes later and glucose determinations before and after injection. Immediately after operation and at intervals during the next 16 days the same determinations were made. As a rule no increase of respiratory quotient could be obtained, or at most only a very slight one. In other words, it was found that glucose in the body of a patient operated upon is not burned up in the usual manner. This disturbance of metabolism was observed for approximately a week, that is, during the period which may be termed critical clinically. It seems to point to lack of resistance to the operative trauma, which is the more worthy of note in view of the fact that both physically and psychically conditions were such as of themselves to produce an increase of metabolism without glucose administration. It was also noted that there was no increase of lactic acid in the first 4 hours after operation, as might have been expected, but on the contrary there was a clear decrease. The injected glucose was therefore not transformed into lactic acid. The result could clearly not be attributed simply to a supporting of the liver or heart muscle function, but evidently had to do rather with an activation of mesenchymal cell functions. To prove this a small bit of liver was taken from each patient immediately after opening the abdomen and before the glucose injection, and another bit was removed 30 minutes later. Histologic examination revealed changes in the Kupffer cells following the glucose injection, which could be regarded as the expression of a cell irritation and of increased cell function. They point to an activation of the reticulo-endothelial system, which seems adapted to explain the therapeutic effects of intravenous glucose injections.

Acute Mercury Poisoning: Report of Twenty-One Cases with Suggestions for Treatment.—B. I. Johnstone tabulates the data in 21 cases of acute mercury poisoning treated at the Henry Ford Hospital from 1918 to 1928. The majority of the patients were young adults, with an average age of 30.8 years. The

mortality was 14 3 per cent Two of the deaths followed vaginal douches The amount of mercury ingested (usually the bichloride), in so far as it was possible to estimate it varied from 0 75 to 27 grams From the practical standpoint more depends upon the amount of the drug absorbed than upon the quantity ingested In the treatment an early start is the important feature Efforts should be chiefly directed toward prevention of absorption, as we have not as yet any effective antidote after the drug has reached the circulation Before the physician arrives repeated vomiting has already removed a considerable portion of the drug, and possibly protein has been given in the form of eggs and milk If so, the stomach should be immediately washed out with a saturated solution of sodium bicarbonate, at least two quarts being used Immediately after the gastric lavage a duodenal tube is passed and transduodenal irrigation carried out with sodium bicarbonate until the patient expresses a desire to defecate This occurs after one or two quarts has been given In this way the whole intestinal tract is washed out One ounce of a saturated solution of magnesium sulphate should be left in the duodenum before withdrawing the tube The patient is kept on a high carbohydrate, maintenance protein, low salt diet Six ounces of milk, alternating with 2 ounces of lactose in 6 ounces of fruit juice are given every two hours An effort is made to administer at least 5,000 c c of fluid every twenty-four hours Within a few hours after ingestion, the salivary glands, gastric mucosa, and large intestine begin to excrete mercury To prevent reabsorption, stomach and colon lavage are repeated twice a day and duodenal lavage once daily In addition, biliary drainage is carried out for several hours until 500 to 600 c c of bile has been drawn off If the food and fluid intake becomes low with increasing toxicity, fluids should be given parenterally with glucose to maintain the carbohydrate intake Sodium thiosulphate is taken frequently by mouth and also is given intravenously Intensive therapy should be continued so long as an appreciable excretion of mercury occurs —*Canadian Medical Association Journal*, April, 1931, xxiv, 4

Glycerin Injections in Treatment of Varices by the Sclerosing Method—F Maignon, Ch Grandclaude, and M Lambert, writing in the *Bulletin de l'Academie de Medecine* of March 7, 1931, report that injections of 3-5 c c glycerin, slightly diluted for convenience, if necessary, into the saphenous vein of the dog have a sclerosing effect In 2 of 17 animals injected, there was complete obliteration of the vein after the first injection in another 2, incomplete obliteration, and in 7, a slight thickening of the walls with lymphocyte infiltration, in 6 there was no reaction But two such injections, with an interval of 7 to 10 days between, caused obliteration of the vein 7 times in 7 The first injection apparently serves to sensitize the walls of the vein for the second, which results in induration of the tunics, with formation of an organized thrombus at the level of which metamorphosis of the fibrin into collagen takes place over a certain tract around the point of injection It is as if a local anaphylaxis were produced, but the authors think that the glycerin acts not as a sensitizing substance *per se*, but as one capable of exerting a mortifying effect upon a part of the protoplasm of the cells it contacts, with the result that the dead proteins have all the effect of a sensitizing injection The glycerin should be considered a nutritive element, existing normally in the economy of the body, since it represents a product of fat reduplication It owes its indurating properties solely to its concentration Diluted in the blood, it loses all its injurious properties and becomes a food, which is not the case with quinine, urethan, sodium salicylate, etc, when used for varices These substances not only do not produce perfect obliteration with the same dependability as glycerin, but they sometimes cause unfavorable constitutional symptoms immediately after injection, and, later on, large necrotic areas around the veins Attempts to carry out the glycerin procedure on human beings have confirmed in every way the results obtained in dogs The injections are entirely painless and have never produced any functional disturbances

The Study of Symptoms—In the diagnosis of disease John A Ryle is persuaded that with the growth of experience the first place is often given to symptoms, which may not only be earlier but more eloquent than signs Symptoms express a disturbance of function While not specific for diseases they are specific for functional errors, and these errors, for the most part, depend upon an exaggeration, a depression, or an inhibition of normal reflex phenomena The question which one should constantly ask is *"What does this symptom mean?"* not *"What is it a symptom of?"* As a guide to the investigation of subjective phenomena Ryle reviews the methods employed in a study of the significance of colonic pain, nausea, and the feeling of impending dissolution In the case of colonic pain the queries concern the character of the pain, its degree, its situation, its localization or extent of diffusion, its paths of reference, frequency, time of occurrence, duration, and its aggravating and relieving factors These are correlated with associated symptoms, such as constipation, diarrhea, dysmenorrhea, urinary frequency, and "dead fingers" in cold weather The chief objective finding is a readily palpable and firmly contracted colon due to tonic rigidity Sigmoidoscopic and roentgenologic examinations may add confirmatory evidence of spastic colon This method diminishes the margin of error in differentiating an important neurosis from appendicular disease,

duodenal ulcer, diverticulitis, carcinoma coli, renal and biliary colic, ovarian and tubal disease, and hypochondria. In the case of nausea the method is to consider common experience, the physiological and pathological provocatives of the symptom, the various disorders in which it is prominent, and the factors common to these. Finally aid is obtained from *x*-ray studies of the stomach during bouts of natural and induced nausea. With the "sense of dying" symptom the method is to consider the known conditions in which it occurs, to record and correlate associated phenomena in each of these, to advance the hypothesis that the symptom can best be explained as being due to some disturbance involving the neighborhood of the vagal nuclei, the realm that governs the functions of life itself. A practical outcome of these considerations, apart from their contribution to diagnosis, is that, excepting in angina pectoris of organic origin or in disease of the medulla itself, the alarming sense of dying has no prognostic significance. The methods in brief are those of observation, record, and analysis. While the results lack the finality of successful experiment, they are, nevertheless, scientific and serviceable.—*The Lancet,* April 4, 1931, ccxx, 5614.

Early Diagnosis and Immune Therapy of Neoplasms.—According to Francesco Figaro, the enzyme reaction discovered by certain Italian workers (Sivori, Rebaudi and Menniti) has made it possible to establish the presence of specific defensive ferments in the blood of subjects who are carrying tumors. It consists in placing in contact with the serum of the patient a protein antigen, not in its integrity as in the Abderhalden reaction, but after it has been subjected to hydrolysis, up to the point at which all it has to overcome is the last stage of disintegration from polypeptids into amino-acids. It is based on the new principle of the conservation of the biologic specificity of the albuminoid molecule even in its last stages of disintegration. All that it has in common with Abderhalden's method is its use of ninhydrin. The name *disintegrates* or *ultrapeptones* has been given to the antigens thus prepared. When a very small quantity of serum from a cancerous subject is placed in contact with the disintegrate coming from a neoplasm of the same type and site, in the state of ultrapeptone, a digestive process is observed in the mixture, which transforms the ultrapeptones into amino-acids, whereas this does not occur in control serums of healthy subjects or of those affected with other diseases. The more recent the neoplastic formation, the more pronounced was the reaction toward the tumor. Conversely, when the organism was profoundly intoxicated by the tumor, and a prey to cachexia, the diminution of specific ferments was demonstrated by a weaker or even a negative enzyme reaction, the neoplastic toxemia having overcome the patient. It has been demonstrated experimentally that ultrapeptones obtained from sarcoma of the Norwegian mouse inoculated into the rat in advance of a graft of sarcoma inhibit development of tumors in the animal. Previous inoculations of the pulp of non-disintegrated sarcoma, however, do not in any way modify the course of the grafted tumor. Treatment of sarcoma with ultrapeptone slows down the development of such tumor. Injection of neoplastic ultrapeptones into healthy animals causes production of ferments that are specific against the corresponding tumors. If, for example, they are obtained from a mammary cancer, the enzyme reaction is strongly positive for mammary cancer, less intense for cancer of the stomach, uterus, etc., and vice versa. These results in animals led to tests of the therapeutic effects in human beings. Results may be said to be very encouraging in 9 cases of skin epitheliomata, in one of which cure has persisted for over a year. Improvement is also observed in 3 cases of mammary cancer, 2 of gastric and 1 of rectal cancer which are receiving the treatment.—*Riforma medica,* March 16, 1931.

Mumps Meningitis.—This not altogether infrequent complication of mumps finds its incidence chiefly in young children according to Karl Holtz, and becomes increasingly rare with advancing years. So polymorphic is it that some cases pass unnoticed until severe sequels and an accompanying inflammation of the central nervous system cause a review of the history. Holtz reports what is a most unusual case occurring in a peasant woman, 39 years of age. Beginning with swelling of the right cheek and with headache, its most striking symptom was the rapid loss of speech, followed by somnolence and unconsciousness. The temperature never rose above 37.8°C. (100°F.), and the pulse was always 70-80. There was slight rigidity of the neck, with such other indications of a cerebral process as pupillary disturbances, ptosis, and spasms of the masseter. A lethargic-ophthalmic encephalitis was excluded by absence of sleep disturbances, of increased salivation, etc. Characteristic symptoms of epidemic meningitis, such as perspiration, articular swelling, etc., were also lacking. Lumbar puncture gave exit to a purulent fluid exhibiting first a polynucleosis, then for the most part a lymphocytosis, and finally a pure monocytosis. This finding, however, cannot be regarded as excluding a parotid meningitis. The fact that in mumps a lymphocytosis is so frequently found in the cerebrospinal fluid leads the author to conclude that here the meningeal reaction is in most cases so rapid and runs such a favorable course that the preliminary polymorphonuclear stage escapes notice. Possibly it is found only in the first stage as in this case. A warning is uttered against judg-

ing the etiology of meningitis from the cell reaction of the spinal fluid without due regard to its phase, which changes just as is the case with regard to the blood. The punctate examined on 4 occasions in this case never contained any microorganisms, thus easily excluding a cerebral abscess. There could be no doubt that this was a parotid meningitis, although the source of infection remained unknown. The case resulted in cure, with gradual return of faculties requiring a period of several months.—*Deutsche medizinische Wochenschrift*, March 27, 1931.

Activated (Irradiated) Fluorescein in the Treatment of Cancer.—In a paper by S. Mockton Copeman, Frank Coke, and Dr. Gouldesbrough, published in the *British Medical Journal* in August, 1929, a method of treatment was described which had afforded satisfactory results in certain cases of cancer. It consisted in the use of a slightly alkaline solution of the sodium salt of fluorescein sprayed or painted widely over the surface of the growth and followed by the application of radium or *x*-rays of moderate penetration. Copeman now reports the results of this treatment in a total of 120 patients with carcinoma treated at the Royal Northern Hospital. Of these 33 have died and 23 have recovered and remained well, some for more than three years. Excellent results have been obtained in certain cases of cancer of the breast. In some cases the superficial application of fluorescein sufficed, but for more deeply seated growths, in which there was reason to suspect dissemination of the disease, the fluorescein was also given orally or intravenously. Owing to the extremely low toxicity of the drug, considerable quantities may be administered in one or the other of these ways. The ordinary dose by mouth is two capsules of 7½ grains each (15 grains or 1 gram in all). For intravenous use 20 c.c. of a sterilized 5 per cent. solution of sodium fluorescein is slowly injected. The object of giving the drug internally is to bring under its influence, on irradiation, outlying cells which may have become affected, or an organ like the liver, which may be suspected of harboring secondary deposits. There is reason to hope that by giving the fluorescein internally as well as by local application, together with proper distribution of the subsequent irradiation, recurrence of cancer may be prevented, not only locally but generally. That the results are not entirely due to the radium or the *x*-rays is indicated by the fact that success has been attained in cases that were considered inoperable, and in which radium and the *x*-rays had failed. Encouraging results with this treatment have been reported from a number of London hospitals. A preliminary investigation of salts of the rhodamine group and the sodium salt of dichloroanthracene·disulphonic acid affords some evidence that the anthracene salt, when irradiated, is capable of exerting a lethal effect on malignant cells exceeding that of fluorescein.—*British Medical Journal*, April 18, 1931, i, 3667.

Cardiac Hormone Therapy with a Muscle Extract in Angina Pectoris and Essential Hypertension.—On the basis of 70 cases treated, Korach says that he has had excellent results from the use of an extract of muscle, in severe cases both of true angina pectoris and pseudoangina. In every case all other forms of medication were laid aside in order to give the new treatment a thorough test. To secure as prompt action as possible, subcutaneous or even intravenous administration was employed. Within 15-20 minutes after subcutaneous and even more quickly after intravenous injection, the agonizing spasm with pain radiating into the back and left arm was relieved, and with astonishing promptness there was a diminution of the dyspnea proceeding from the visceromotor reflexes of the chest musculature. Patients who just before the treatment had dreaded to make any least movement were shortly afterwards in a condition to leave the bed and walk about the room without pain. Objectively the effect of the muscle extract was shown in a slowing down of the tachycardia and a fall of systolic blood pressure amounting to 1030 mm. Hg in cases where an increase had appeared during the attack. There was a markedly good effect also on the so-called "chronic stenocardia" in long-standing cases of effort angina in which attacks were excited by movements, by going from a warm room into a cold one, facing a strong wind, etc., in patients accustomed to the use of nitroglycerin tablets for quick relief. In such cases the effects of an injection of 2 c.c. lasted on an average for 24 hours. When the pains returned, they were not, according to the patients, so severe. Prophylactic evening injections prevented night attacks more effectively than nitroglycerin tablets. Complicated cases should have absolute rest in bed, with intramuscular injections twice a day of 1½ to 2 c.c. each. These are reduced to 1 c.c. after 2 weeks have passed without an attack, and at the end of 3 weeks 1 injection daily suffices; finally treatment is peroral. The hypotonic effects observed induced the author to make use of the remedy in cases of essential hypertension, with astonishingly good results in some cases, but with occasional failures.—*Münchener medizinische Wochenschrift*, March 20, 1931.

LEGAL

SUPREME COURT RULES ON FREEDOM OF THE PRESS

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

One of the most recent rulings handed down by the Supreme Court of the United States seems to your Counsel to be of such general interest that it is appropriate to devote to it space in these columns. That is the decision just rendered declaring the so-called Minnesota "gag law" unconstitutional. The opinion of the majority of the Court was delivered by Chief Justice Hughes. Concurring with him in the opinion were Justices Holmes, Brandeis, Stone and Roberts, the other four Justices dissenting.

The statute in substance provided for the abatement as a public nuisance of the business of publishing a "malicious, scandalous and defamatory public newspaper, magazine or other periodical." A weekly newspaper was brought under the operation of this law upon charges that it had published articles concerning certain local public officers and concerning certain other newspapers, charging among other things in the allegedly objectionable articles that the said public officers were guilty of neglect of duty, were associated with gangsters, indulged in grafting, and the like. There was no question as to the fact that the articles made very serious accusations against the named persons and that, if untrue, the newspaper could have successfully been made the defendant in actions to recover damages for libel for injury to reputation. It, on the other hand, seems clear that under the statute it would have been a complete defense to such a legal proceeding if the newspaper established to the satisfaction of the tribunal that the charges printed by it were both true and published with good motives and for justifiable ends.

The prosecution under the statute proceeded on the theory that even though the matter published might have been true, the newspaper was legally liable to be suppressed on grounds that it was malicious, scandalous and defamatory. This theory was challenged as an invasion of the rights of the freedom of the press as guaranteed by the United States Constitution.

The proceedings taken against the newspaper finally resulted in a decision by the highest Court of the State of Minnesota determining that the judgment was valid which declared the newspaper a public nuisance and perpetually enjoined its owners "from producing, editing, publishing, circulating, having in their possession, selling, or giving away any publication whatsoever which is a malicious scandalous, or defamatory newspaper as defined by law" and also "from further conducting said nuisance under the name and title of said 'The Saturday Press' or any other name or title." From the judgment thus affirmed, an appeal was taken to the Supreme Court of the United States.

As the Court pointed out, "It is no longer open to doubt that the liberty of the press, and of speech, is within the liberty safeguarded by the due process clause of the Fourteenth Amendment from invasion by State action. It was found impossible to conclude that this essential personal liberty of the citizen was left unprotected by the general guaranty of fundamental rights of person and property." With that as a premise, the Court proceeded to clearly point out the manner in which the fundamental rights of freedom of the press had been invaded.

As to the object of the statute, Mr. Justice Hughes speaking for the majority said: "The statute is not aimed at the redress of individual or private wrongs. Remedies for libel remain available and unaffected * * * It is aimed at the distribution of scandalous matter as detrimental to public morals, and to the general welfare, tending to disturb the peace of the community and to provoke assaults and the commission of crime."

That the Court felt that the means adopted by the statute to achieve such an end were improper and unsuited to their purpose, is clear from the words of the opinion: "If we cut through mere details of procedure, the operation and effect of the statute in substance is that public authorities may bring the owner or publisher of a newspaper or periodical before a judge upon a charge of conducting a business of publishing scandalous and defamatory matter—in particular that the matter consists of charges against public officers of official dereliction—and unless the owner or publisher is able and disposed to bring competent evidence to satisfy the judge that the charges are true and are published with good motives and for justifiable ends, his newspaper or periodical is suppressed and further publication is made punishable as a contempt. This is the essence of censorship. * * *

"The fact that for approximately 150 years there has been almost an entire absence of attempts to impose previous restraints upon publications relating to the malfeasance of public officers is significant of the deep-seated conviction

that such restraint would violate constitutional right Public officers, whose character and conduct remain open to debate and free discussion in the press, find their remedies for false accusations in actions under libel laws providing for redress and punishment, and not in proceedings to restrain the publication of newspapers and periodicals * * *

'The fact that the liberty of the press may be abused by miscreant purveyors of scandals does not make any the less necessary the immunity of the press from previous restraint in dealing with official misconduct Subsequent punishment for such abuses as may exist is the appropriate remedy, consistent with constitutional privilege * * *

"Equally unavailing is the insistence that the statute is designed to prevent the circulation of scandal which tends to disturb the public peace and to provoke assaults and the commission of crime Charges of reprehensible conduct, and in particular of official malfeasance unquestionably create a public scandal, but the theory of the constitutional guaranty is that even a more serious public evil would be caused by authority to prevent publication

"To prohibit the intent to excite those unfavorable sentiments against those who administer the Government, is equivalent to a prohibition of the actual excitement of them, and to prohibit the actual excitement of them is equivalent to a prohibition of discussions having that tendency and effect, which again is equivalent to a protection of those who administer the Government, if they should at any time deserve the contempt or hatred of the people against being exposed to it by free animadversions on their characters and conduct"

This decision will undoubtedly provoke criticism on the supposition that it paves the way for unrestrained yellow journalism and gives the tabloids a chance for more sensationalism than ever, but such an argument is unfounded for, as the Court pointed out, the remedies to check the dissemination of untruths are still present and can be called upon to check such evils

---

ALLEGED NEGLIGENT TREATMENT OF FRACTURE OF ARM

A patient consulted the defendant doctor complaining of an injury to his arm, stating that he had fallen heavily upon it

The doctor examined the arm by manipulation and failed to find any evidence of a fracture and suggested that the patient have X-ray pictures taken The next day the patient returned to the doctor with the X-ray pictures and the following report

"Incomplete comminuted fracture through the head of the radius Fragments present good ap position"

The doctor then applied to the arm a Plaster of Paris splint, both anterior and posterior immobilizing the arm in a right angle position

The patient returned to his home and three days later again consulted the doctor, at which time the swelling of the arm was down considerably and the splints loosened The doctor reinforced the splints with adhesive plaster on that occasion and on subsequent occasions A few days thereafter when consulted by the patient the treatment given by the doctor was removing the splints and heating the arm with a lamp, massaging it and re applying splints

Sixteen days after the first treatment the doctor finally removed the splints and stayed the patient's hand in his vest From time to time, for about six weeks from the removal of the splints, the doctor continued to treat the patient, giving him massage, heating his arm by lamp, and passive motion, and at the end of that time suggested that the patient consult a masseur When the doctor saw the man last his arm was much improved and he then was able to extend his arm about 155 degrees At that time the patient provided the doctor with an X-ray picture which showed perfect union

The doctor did not again see the patient, as he left for his vacation, referring the patient to another doctor who attended his practice in his absence The patient, however, did not return to the doctor for treatment again, and instituted an action in the Supreme Court against the doctor to recover on a claim of malpractice A notice of appearance was served on behalf of the doctor, but no complaint was ever served in the action After some time, through the efforts of your counsel, the attorney for the plaintiff was persuaded that the doctor had in no way departed from the proper and approved practice and obtained the consent of the plaintiff's attorney to discontinue the action Thus the matter was terminated in favor of the doctor without trying the case

BURN CLAIMED CAUSED BY NEGLIGENT PHYSIOTHERAPY

The doctor who was the defendant in a recent case, specialized in physiotherapy. A patient consulted him complaining of rheumatism, and after examination the doctor advised a certain form of physiotherapy. The machine used by the doctor was a standard make machine which may roughly be described as resembling an ordinary bed with a canopy attached over it. On the underside of this canopy were thirty-two electric bulbs of 20-watt strength. The treatment table was designed so that it could be drawn from under the canopy for the patient to be placed on or removed from the table. When in place for treatment, the apparatus enabled the body of the patient to be treated by radiation from the bulbs, extending from the patient's feet to his neck. The patient's body, disrobed, was a distance of twelve to eighteen inches from direct contact with the electric bulbs.

This patient received a series of treatments by means of the said machine, which were each of twenty minutes duration. On one such occasion, after the patient had received about a five minute application, he called to the nurse standing nearby that he had burned his toe. The doctor examined the patient's foot but found no evidence of a burn. A few days later when the patient called for his next treatment he had a blister on his foot which the doctor opened, and dressed with a wet dressing. The patient continued to undergo the light treatments and when last seen by the doctor appeared to be practically healed. The doctor contended that the machine was in perfect order and that the only way the patient could possibly have received the burn was by raising his leg so as to strike one of the electric bulbs. The patient had been cautioned against this.

Some time later a suit was commenced charging that the doctor was negligent in his treatment of the plaintiff, and attempting to recover large damages for the burn sustained by the patient, claiming that amputation of the toe had become necessary.

Before the case could be reached for trial the plaintiff died, however, and the action was marked abated, thereby closing the matter.

ALLEGED NEGLIGENT TREATMENT OF INJURY TO CHILD'S FINGER

A child, two years of age, was brought to the office of the defendant doctor, and the mother of the child informed the doctor that while playing with a lawn-mower he had cut his right thumb.

The doctor found that the tip end of the thumb had been pinched off and was hanging by a shred. The doctor took a 2% solution of mercurochrome and cleansed and sutured the wound with two horse-hair sutures, and applied a dry sterile bandage. When the doctor treated the wound it showed a clean cut with no signs of dirt or infection present.

Two days later the child was brought back to the doctor and again the wound was found clean and no infection present. The sutures were holding, but the extreme tip of the finger was dry. Mercurochrome was again applied and the finger dressed and the child taken home. Two days subsequent to said treatment the child was again brought to the doctor and conditions were the same and the same treatment was given.

The following day when the child was brought to the doctor a small amount of pus was found in the suture line. The sutures were removed and a necrotic piece of the extreme end of the finger was clipped off. The finger was dressed with 8% aluminum acetate and a gauze bandage applied. The next day the wound was again cleaned and found to be granulating nicely, and balsam of Peru was applied with a bandage.

The mother at that time stated that the child complained of a sore throat, which the doctor examined with the aid of a tongue depresser, but nothing abnormal was found and the child was not running a temperature. The following day the doctor was informed that the child had been taken to a hospital where he subsequently died from tetanus.

On the doctor's first examination no dirt was found in the wound and there was not present any indication that tetanus might levelop. The wound had bled freely and the sutures used did not shut off free drainage, nor hermetically seal the repair.

A suit was instituted against the doctor, charging that the treatment he had administered to the child was responsible for death of said child. The case was duly brought on for trial before a Judge and Jury, and after the issues in the case had been submitted to the Jury they returned a verdict in favor of the defendant.

NEWS NOTES

THE ANNUAL MEETING

The annual meeting of the Medical Society of the State of New York was held on the first three days of June in the Hotel Syracuse, Syracuse, N. Y., according to the plans and programs announced in this Journal of April 15th. It is always desirable to house all the features of the annual meeting under one roof and on one floor. The ideal place was formerly the Waldorf-Astoria Hotel in New York, for there all features of the meeting were accommodated on the second floor; but since that hotel has been discontinued, few other hotels in the State can be found suitable. The Hotel Syracuse approached the standard closely, and the managers put forth every effort to serve the visitors courteously and efficiently.

The registration was a little over 750 which is somewhat smaller than usual, owing to the near approach of the meeting of the American Medical Association, and the sessions of the National Ophthalmological Society and other organizations. However, those who came to the State meeting took a deep interest in the proceedings as was shown by the well filled rooms of the general sessions and the scientific sections. Possibly the reduction in the number of those in attendance was also due to the absence of many physicians who sought pleasure principally.

HOUSE OF DELEGATES

The annual meeting of the State Society opened with a session of the House of Delegates at two o'clock on the afternoon of the first of June, with the Speaker, Dr. John A. Card, of Poughkeepsie, presiding. The harmony and expedition with which the business was conducted were largely due to his decisions, which were given promptly, humorously and on a broad, liberal basis.

The House is composed of about two hundred members, consisting of one hundred and fifty delegates elected by the county societies, and the officers of the State Society and past-presidents. The attendance was exceptionally good, only about a dozen badges prepared for the members not being used.

The proceedings of the House of Delegates were conducted with harmony and entire good feeling. While there had been suggestions of protests from some county societies, the subjects were of a minor nature and were usually settled with a frank admission of their debatable character which required future study. The satisfactory settlement of these problems, or their future study, was due largely to the inclusion of the officers and past-presidents of the State Society in the membership of the House of Delegates, thereby combining the representative character of the county societies with the mature wisdom and experience of the State officers.

Practically every subject in dispute had been considered by some committee of the State Society, and the discussions had been published in the Journal at intervals throughout the year.

A further incentive to harmony was the publication of the reports of the officers and committees, and also of the personnel of the reference committees, in the Journal of May first, a full month in advance of the meeting. Seventy-five delegates had been appointed to fifteen reference committees, and only five changes in personnel were necessary, all because of unavoidable absences. The result was that the members had a month to consider the reports and recommendations of the officers, and were therefore prepared to make definite suggestions for action as soon as the House of Delegates convened.

The House showed its confidence in its officers and committees by adopting nearly all their recommendations. The harmony and wisdom shown by the delegates were due largely to three committees whose activities, and even existence, began scarcely five years ago. These committees —that on Public Health and Medical Education, that on Public Relations, and that on Economics —had been continuously active throughout the year, and had given serious consideration to subjects which had previously come up only in the House of Delegates and had been sources of discord among delegates who had little experience in the solution of the problems.

An action of major importance was the approval of the suggestion of President Ross that the State Society take steps to organize the work of popular medical publicity through the newspapers, the radio, and the lecture platform, as Indiana, Minnesota, and other States have done successfully. (Reports of the work of popular medical publicity in the other States will be found in the Journal in the Department of "Our Neighbors," the articles being listed in the annual indexes under the title "Popular Health Education.")

The election of officers was unusually har-

monious, not a single contest taking place. The new officers will be found listed in the Journal on the first editorial page where they will appear in every issue throughout the year, as in previous years. It is probable that the members consult this page more frequently than any other, as they frequently have occasion to ascertain the identity of an officer or committee chairman.

The sessions of the House of Delegates were held on the afternoon and evening of June first, with a social supper in between. The House finished its deliberations on the morning of the second day. The full minutes of the proceedings, including brief outlines of the debates, will be printed in this Journal of July first.

The House of Delegates also approved the suggestion of President Ross that each County Society should appoint a reporter whose duty would be to represent the *New York State Journal of Medicine* in collecting and forwarding medical news, particularly that of the meetings of the societies. The matter of printing news of county societies were also brought up independently by a delegate from a large city who complained erroneously, that news from his society was not published. Dr. Orin S. Wightman, Editor-in-Chief of the Journal, replied that all news received from county societies was published, subject only to the usual editing; and that the Editors and Publication Committee were putting forth every effort to secure and print the news from every county society. (See page 768).

THE ANNIVERSARY MEETING

The charter of the Medical Society of the State of New York requires it to hold an anniversary meeting each year. This year the meeting took the form of a banquet and after-dinner speaking, on the evening of the second day of the sessions. The occasion was successful to an unusual degree. The banquet room was filled to its capacity, and the speaking was of peculiar interest. The toastmaster was Dr. Frederick H. Flaherty, of Syracuse, Chairman of the Committee on Arrangements.

The first speaker was Dr. William Gerry Morgan of Washington, President of the American Medical Association, who gave a paper on the subject "Are the Widespread Criticisms of the Medical Profession Justified?" This paper is printed on page 739 of this Journal.

The annual Presidential Address was given by Dr. William H. Ross who discussed "Medical Responsibilities" from the standpoint of his broad experience as President during the past year. This address is printed as the leading article in this issue of the Journal.

Dr. Wingate Todd, Professor of Anatomy in the Western Reserve School of Medicine, Cleveland, Ohio, gave an address on the subject "Comings and Goings," illustrated with lantern slides taken from classic pictures. The subject referred to the development and the death of human beings, and consisted of a discussion of the relative influence of heredity and environment in the growth of the child. While Dr. Todd was thoroughly scientific, he was also literary and artistic in his presentation of his subject. The form and substance of his address were ideal for an after-dinner address to an audience of doctors and their wives.

The anniversary meeting closed with felicitous greetings from the new President, Dr. William D. Johnson, of Batavia, and the President elect, Dr. Charles Gordon Heyd, of New York, Past Treasurer of the Society.

THE SCIENTIFIC SESSIONS

While the administrative business of the Medical Society of the State of New York is transacted in a formal way in the House of Delegates by delegates regularly chosen, the great majority of those attending the annual meeting come for the purpose of attending the scientific sessions in order that they may learn about the newer methods of practice and gain inspiration from the presence of outstanding practitioners of medicine. Following the successful precedent of last year, the Committee on Scientific Work, under the chairmanship of Dr. Arthur J. Bedell, of Albany, arranged a program for general sessions on the afternoons of the second and third days of the meeting. That on Tuesday afternoon was a symposium on Psychopathology and Psychotherapy, with the following speakers:

Dr. Frankwood E. Williams, New York, "In Childhood and Adolescence."

Dr. Abraham A. Brill, New York, "In Neuroses and Phychoses."

Dr. Smith Ely Jelliffe, New York, "Internal Medicine."

The program of Wednesday afternoon was a symposium on "Head Injuries" with the following speakers:

Dr. Wells P. Eagleton, Newark, N. J., in "Injuries to the Frontal and Temporal Region from a Physiological and Anatomical Standpoint and Their Relation to the Development of Meningitis."

Dr. Albert G. Swift, Syracuse, "Treatment of Head Injuries."

Dr Foster Kennedy, New York, "Treatment and After Effects"

The mornings were given over to meetings of the eight scientific sections which are listed, together with their officers, on the first editorial page of each issue of the Journal In addition the special committee on Physical Therapy held a scientific session on the morning of June third, with the chairman, Dr Richard Kovacs, of New York, presiding

In accordance with the rules of the Medical Society of the State of New York, the papers of the scientific sessions will be published in the Journal during the coming year Since seventy-two papers are listed, an average of three papers will appear in each issue of the Journal

THE TECHNICAL EXHIBITS

No meeting of a State Medical Society is complete without an exhibit of the manufacturers who supply the tools with which a physician works The practice of modern medicine differs from that of a half century ago, principally in the use of instruments of precision, and of drugs, chemicals and foods of known potency All the available floor space was occupied by thirty-four exhibitors whose names and products are listed in the April fifteenth issue of this Journal

It has been the policy of the officers of the Medical Society of the State of New York, and of the members of the editorial staff of the Journal to establish friendly relations with the exhibitors, and so, following the example of past meetings the members of the exhibitors staffs, some seventy-five in number, were tendered a dinner and entertainment given on the evening of June first in a room adjoining the exhibit booths There was also after-dinner speaking under the direction of Dr Orrin Sage Wightman, editor-in-chief of the Journal The speakers included Dr W H Ross, retiring President of the State Society, Dr W D Johnson, incoming president, and Dr Charles Gordon Heyd, President elect, Dr Frank Overton, executive editor, and Mr J B Tufts, advertising manager

Replies were given by Dr Lillian B Storms, representing the Gerber Products Company, maker of strained vegetables for children, and by Mr H Brandon, President of the Anglo French Drug Company, New York

---

GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The disorders of the circulatory system, which have in the last decade placed "heart disease" in the forefront of the principal causes of death, will constitute the theme of the Fourth Annual Graduate Fortnight of The New York Academy of Medicine

This graduate course of instruction will consist in a series of lectures and clinical demonstrations, concentrated in a period of two weeks from the 19th to the 30th of October, 1931

Lectures will be delivered evenings in the auditorium of The New York Academy of Medicine, 2 East 103rd Street, New York City Clinical demonstrations will be held during afternoon in twelve of the leading hospitals of the city The demonstrations will be in charge of teaching clinicians and will be organized so that those participating will have the full benefit of individual contact with both demonstrator and patient

An outstanding feature of the 1931 Graduate Fortnight will be the anatomical, bacteriological, and pathological exhibition of specimens and research material bearing upon the subjects dealt with in the evening meetings and clinical demonstrations

This exhibit will be housed in the Academy and will be open for leisurely study A number of the exhibited items will be demonstrated on schedule and subjected to group discussion

The profession of the country is invited to attend and to participate in the Graduate Fortnight There is no charge for attendance at any of the clinics or meetings, but registration for the clinical demonstrations is required

A complete program and registration blank for the clinics and demonstrations may be secured by addressing the New York Academy of Medicine, 2 East 103rd Street, New York City

COMMITTEE ON PUBLIC RELATIONS

A meeting of the Public Relations Committee was held in the Albany office on Thursday, May 21, 1931. Those present were Drs. Sadlier, Johnson, Fisher, Hambrook, Ross, and Lawrence.

Under "unfinished business" Dr. Sadlier reported that he had received replies from five deans of medical schools to the letter he had written, asking their interest in informing the medical students upon the provisions of the public welfare law. Two of the deans—Dr. Ordway of Albany, and Dr. Burrett of Homeopathic—asked him to lecture to their students upon the subject. Appreciation was expressed by the committee on the responses, and it was recommended that Dr. Sadlier arrange to have a lecture deliverel upon the subject to the students of these two schools. If there is not sufficient time to prepare for such lecture this year, then it should be made a part of next year's program.

Dr. Lawrence reported that during the last two weeks he has visited with the presidents and secretaries of several County Societies and discussed with them the affairs of their Societies. These conferences have been exceedingly valuable; the presidents and secretaries invariably have expressed their appreciation of an opportunity to discuss with the Executive Officer their programs of activities. They have all shown a keen interest in developing work along the lines suggested by the Public Relations Committee, but in several instances the committees have not been as active as they should, owing, it was discovered, to the fcact that they did not have a clear conception of what they might do; for instance, in Greene County the chairman had not named other members to his committee, but being present at the conference he was so convinced of the opportunities presented that he immediately named a committee which received the approval of the president and secretary, and outlined a program of activities for the next year.

In most instances the administration of the public welfare law is the feature that is engaging their attention at this time. One chairman of a Public Relations Committee expressed dissatisfaction with the report of minutes of the meetings of the State Committee on Public Relations. He suggested that, in his opinion, those minutes should contain more specific suggestions as to what the county committees should do and how they might go about it. This criticism was accepted by the committee as fair and it was recommended that the chairman communicate with the county chairmen individually, making some suggestion to those who have already submitted surveys or reports of activities as to ways in which they might further advance their work, and a special request should be made of the chairmen from whom no survey or statement of activities has been received, asking for a statement as to what their committee has done and what future plans of activity they contemplate.

Dr. Fisher moved, seconded by Dr. Hambrook, that the county societies should be urged to have occasional meetings of their committees, and the chairmen be asked to report to this committee the minutes of their meetings. The state committee would like to keep in closer touch with the county committees, realizing a mutual value in closer contact, but is unable to do so except by more hearty cooperation on the part of the county chairmen.

It was also suggested that by this time all county committees should have had a conference with their county and city welfare commissioners with regard to the promotion of welfare work along the lines outlined in the new law. The regulations under which welfare activities are conducted in cities differ from those provided for the rural districts.

In discussing the advantages of a general conference of the county chairmen, it was recommended that next year the committee should hold regional conferences in addition to the general conference. Last year thirty-two county societies were represented at the general conference. In developing new work such as the public relations program, it is difficult to inspire chairmen by means of correspondence alone and it is thought wise that the state committee should make a great effort to give every chairman an opportunity of discussing the subject with the state committee and other county chairmen.

The committee had invited the General Secretary of Associated Industries to the conference, for the purpose of discussing matters that are of mutual interest to the two organizations. The two organizations have been together on previous occasions through the medium of our Economics Committees. On this occasion, however, we tried to limit ourselves to questions of general relationship. His organization, he reported, is very appreciative of the efforts the physicians are making to advance health conditions in industry. He regretted to report that there are still sources of annoyance arising from selfish and careless work done by a few physicians. The number is exceedingly small, but their disregard of the ethical standards of the profession is at times very annoying. He is thoroughly convinced—and he says that his organization is in accord with him—that the Department of Labor should have the benefit of advice from representatives of the Medical Society. He feels that much of what appears to be a lack of cooperation is due to insufficient knowledge of all those involved in the care of injured persons, both on the part of the physicians and the employers. The employer might take a greater interest in securing medical care for his employees and the Medical Society might

take a greater interest in seeing that those who engage in industrial work observe the Principles of Practice as strictly as do other physicians. Industrial management recognizes that it is good business to take the best care of its employees, but it also is aware of the many possibilities and the expensiveness of malingering. There are bound to be certain persons who will enjoy bad health and, unfortunately, such persons will usually find physicians who are willing to assist or encourage them in their delinquency. It was generally recognized that industrial medicine and surgery today have developed to the point where they are almost specialties; certainly many conditions arising often in industry have developed special types of treatment and care. This is demonstrated in the programs of the New York State Society of Industrial Medicine.

Dr. Ross reported that these questions would receive considerable attention from the sub-committee on medical care of the Governor's industrial investigating committee. It has been suggested to the sub-committee that there should be in connection with the Department of Labor a Supreme Court of Review of Cases, and he thought that an advisory council might meet the conditions better.

The next meeting of the committee will be held in Albany on Tuesday, June 30th, at which time the subject and date for the annual conference of the chairmen of the County Chairmen of Public Relations Committees will be selected.

SUFFOLK COUNTY

The semi-annual meeting of the Suffolk County Medical Society was held in the Kings Park State Hospital, on April 30th, beginning at noon, with the President, Dr. William J. Tiffany, Superintendent of the Hospital in the chair. There were present forty-two physicians, twenty nurses, and fourteen other guests, mostly wives of the doctors. A business session was first held, followed by a social dinner, and a scientific session in the afternoon.

The Secretary, Dr. E. P. Kolb, reported that the Comitia Minora had held four meetings since the annual meeting in October, and had attended to the routine business of the Society, as was reported in the monthly News Letter of the Society.

The following physicians were elected to membership:

L. Cody Marsh, Kings Park.
Carl W. Cahoon, Bay Shore.
Wilbur S. Stakes, Patchogue.
Patrick L. Smith, Babylon.
D. Farquhar Currie, Shelter Island.
Myron W. Brown, Babylon.

Dr. Frank Overton, Chairman of the Committee on Public Health and Graduate Medical Education, reported that the South Suffolk Chapter of the Red Cross proposed to reestablish a nursing service in the southwestern section of the county, comprising the district from Patchogue to Amityville, and asked for the advice and assistance of the doctors. On motion, the Society approved the plans of the Red Cross, and referred the details of the plan to the Southwide Clinical Society for action. (Later this society, which is practically a district branch of the county society, voted to appoint a committee consisting of one doctor from each village, to advise and cooperate with the Red Cross).

Dr. Overton was also authorized to protest against the application of the Better Health Foundation before the New York State Department of Social Welfare, for permission to establish a clinic and laboratory in Huntington, Suffolk County, for giving the Coffey-Humber treatment for cancer. (Later this permission was denied).

Dr. W. H. Ross, chairman of the Economics Committee, reported on agreements reached with the County Welfare Commission regarding medical treatments given under the New Welfare Law (see this Journal, April 15, 1931, page 426).

Dr. G. A. Silliman, Chairman of the Legislative Committee, reported on the action of the members regarding medical bills before the Legislature.

A committee was appointed on obituaries of Dr. J. S. Ames, of Babylon, Dr. W. S. Bennett of Patchogue, Dr. Charles E. Gibbs of Kings Park, and Dr. Frederick Peterson of Smithtown, all of whom had died since the last annual meeting.

At the scientific session Dr. James N. Vander Veer of Albany explained the plan of the Liaison Committee of the Medical Society of the State of New York, and the State Department of Health, in regard to the cooperation of the county societies in the control of venereal diseases. (This plan is outlined in this Journal of June first, page 712).

Dr. G. C. Matthews of the Kings Park State Hospital Staff, gave a paper on mental hygiene with particular reference to children.

Dr. Patricia Steen also of the Hospital staff, read a paper on mental deterioration following encephalitis.

SENECA COUNTY

The regular semi-annual meeting of the Seneca County Medical Society was held at the Elks' Temple, Seneca Falls, N. Y., May 14, 1931. The business meeting convened at 10 A.M. and the usual routine business was transacted.

Mr. Raymond B. Wells, the Seneca County Commissioner of Public Welfare, was present by invitation, and spoke regarding welfare work in the county. Many questions were asked the Commissioner by the physicians present, in regard to the various phases of welfare work, and were answered by him.

Officers were then nominated for the ensuing year.

After a shad dinner, served at the Gould Hotel at 12:30 P.M., the Society reconvened at 2 P.M. for the scientific session. In compliance with the request of the special committee on Cancer Prevention of the Medical Society of the State of New York, it had been decided to have the scientific session at this meeting devoted to the subject of cancer. The program was as follows:

"The Present Conception of the Etiology of Cancer," by Burton T. Simpson, M.D., Director, New York State Institute for the Study of Malignant Disease, Buffalo, N. Y.

"The Early Diagnosis of Cancer," by John M. Swan, M.D., New York State Executive Secretary American Society for the Control of Cancer, Rochester, N. Y.

The second paper was illustrated by lantern slides, and both papers were received with the greatest attention and interest. In the discussion which followed the reading of the papers, Dr. G. B. Adams, Chief of Cayuga County Laboratory, Auburn, N. Y., helped to bring out some of the important facts by his own familiarity with research work on the subject.

The interest taken by the members in the subject of cancer was shown by a rising vote of thanks which was given to Dr. Simpson and Dr. Swan for their unusually interesting papers, and the meeting was adjourned until the annual meeting in October, at the Willard State Hospital.

WOMEN'S MEDICAL SOCIETY

On June 1, 1931, the Twenty-fifth annual meeting of the Women's Medical Society of New York State convened at Hotel Syracuse, Syracuse, New York.

Officers for 1931 and 1932 were elected as follows:

Honorary Presidents: Mary T. Greene, M.D., Helene Kuhlmann, M.D.
President: Marion S. Morse, M.D.
Vice-Presidents: Mary J. Kazmierczak, M.D., Adelaide Dutcher, M.D., Harriet F. Coffin, M.D.
Treasurer: Anna P. Walsh, M.D.
Secretary: Sophy Page Carlucci, M.D.

Councillors.

1st Dist. Branch—Marie L. Chard, M.D.
2nd Dist. Branch—Mary E. Potter, M.D.
3rd Dist. Branch—Emily A. Pratt, M.D.
4th Dist. Branch—Annette Barber, M.D.
5th Dist. Branch—Ruth D. Moore, M.D.
6th Dist. Branch—Edith M. Wheeler, M.D.
7th Dist. Branch—M. Louise Hurrell, M.D.
8th Dist. Branch—Katherine E. Cornevale, M.D.

Committee Chairmen.

Scientific Program—Isabel Borden, M.D.
Legislative—Florence Sherman, M.D.
Medical Education—Mary T. Greene, M.D.
Public Health—Daisy M. O. Robinson, M.D.
Public Relations—Mary N. Sloane, M.D.
Membership—Clara H. Pierce, M.D.
Resolutions—Alta Sager Greene, M.D.

The business session was followed by a paper on "Priodic Health Examinations" by Dr. C. Ward Crampton. This so interested the members that a Committee on Periodic Health Examinations was established, with Dr. Marion Craig Potter of Rochester as Chairman.

Short addresses were made by Dr. Ross, President of the New York State Medical Society, and Dr. William D. Johnson, President-elect; and also by Dr. Albert Pfeiffer, Director, Division of Social Hygiene, State Department of Health.

The following scientific papers were read:

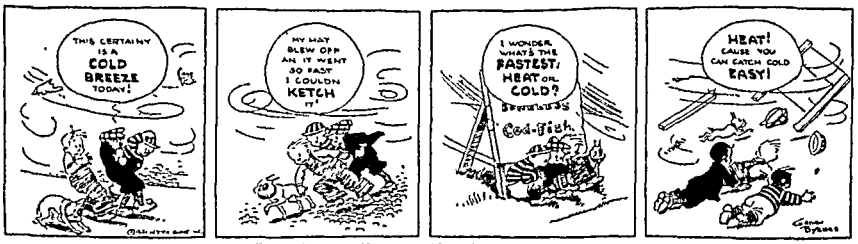
"The Ascheim Zondek Test for Pregnancy." Ida Holzberg, M.D., New York.

"Allergy." Katherine Bayliss McInnes, M.D., Binghamton.

"Breast Tumors." Margaret Warwick, M.D., Buffalo.

"The Influence of Membranes Upon Action Currents." Jane Sands Robb, M.D., Syracuse.

"Ketogenic Diets in the Epilepsy of Childhood." Florence Warner, M.D., Binghamton.



"Child Guidance Problems." Jennie Klein, M.D., Buffalo.

Social events enjoyed by members and their guests included an open house at the home of Dr. Clara H. Pierce, Syracuse, New York, Sunday afternoon, May 31st, and a banquet Monday evening, June first.

SOPHY PAGE CARLUCCI, *Secretary.*

THE DAILY PRESS

Reg'lar Fellers — A Hot Discussion — By Gene Byrnes

From the New York Herald Tribune, April 17, 1931

WOAD

Most well-read doctors will recall woad simply as a dye stuff with which the ancient Britons dyed their faces, but an editorial in the New York *Sun* of May 13 describes its economic importance as the principal source of indigo to Europeans up to a few centuries ago when indigo was introduced from India. The editorial reads:

"Dr. Jamieson B. Hurry of Reading, England, was an inquiring student of natural history as well as an accomplished practitioner of the healing art. He prepared a study of woad and the dye derieved from it—the source of the blue dye with which ancient Britons decorated themselves much as their descendants decorate themselves with rouge. Dr. Hurry's book is posthumously published; it tells the story of economic eclipse of two once important natural dyes.

"Woad was unrivaled as the source of blue dye until the seventeenth century, when importation of indigo from India threatened to supplant it. Indigo triumphed over woad and ruled for years. But in the latter part of the nineteenth century synthetic indigo was produced in the laboratory, and about 1900 economic industrial production became a fact. The indigo men made a strong but losing fight; they introduced improved practices but the chemist got the better of the planter.

Woad and indigo and synthetic blue! What will succeed the aniline as the aniline succeeded the vegetable after one vegetable had succeeded another?"

Woad and indigo are cultivated plants, grown from seed. It is of interest that the American colonists obtained indigo from a wild plant, Baptisia tinctoria, or wild indigo, which decorates the waste lands of Long Island with its two-foot globes of yellow flowers during the summer. When either of the three plants are subjected to watery extraction and fermentation, they yield indican, which is then converted to indigo by processes like the indican test of urine.

SUGAR AND FATIGUE

Professor D. A. Laird, who holds the chair of psychology in Colgate University, has been investigating the effects of food on fatigue with results that are described in the New York *Herald Tribune* of May 8, as follows:

"Sugar had been shown by the Colgate experiments to be the quickest mitigator of fatigue, Dr. Laird said. It also has unsuspected powers, he added, of stimulating gastric juices, thereby aiding digestion. The flow of the gastric juices, experiments showed, tends to fall off before a meal is digested fully. Dr. Laird, therefore, recommends a "second dessert" of candy or cookies about an hour after eating.

"And the old custom of having a sherbet with the heavy meat course was scientifically sound," he said. "The sweet in the sherbet aids in digesting the heavy proteins.

"Dr. Laird's student helpers performed prodigies of industry in studying the flow of saliva, in charting the contractions of the stomach under the influence of the four primary tastes—sweet, sour, salt and bitter—and in testing the effect of nutrition upon fatigue.

"They hiked miles and climbed mountains, munching sweets by the way, in order to explore the scientific variations of that tired feeling—which, they discovered, is not one feeling at all, but fifty-six different tired feelings. They include, it was announced:

Itchiness or creepiness of skin.
Difficulty in relaxing.
Faintness or haziness.
Jumpiness or fidgets.
Inability to recall the name of the man from Seattle.
Wanting not to talk.
Inability to draw a straight line.
Loss of sensitiveness to electric shocks.

"The students ran up hundreds of flights of stairs, swallowed thousands of minute balloons, gulped down Rehfus tubes like spaghetti, and ate the standard "Ewald toast and tea" meal as though they liked it, all for sweet science's sake.

The tests, which still are in a preliminary stage, have dealt primarily thus far, with elementary tastes and foods. In these tastes a standard of intensity, ranged from zero (no taste) to 100 (as strong a taste as the human palate can register).

HEREDITY AND ENVIRONMENT

The relative effects of heredity and environment are discussed editorially in the New York *Times* of May 23, under the title "Nature & Nurture," which says:

"In the debate between hereditarians and environmentalists there is the least disagreement on stature and weight. That both are greatly affected by environment, notably by nutrition, has won sufficiently wide acceptance to be recorded in the elementary textbooks on biology. The case for environment is strengthened by a new set of figures from Harvard and Vassar. An examination of 2,000 pairs of fathers and sons and 500 pairs of mothers and daughters shows a marked gain in height and weight for the children over the parents. In the case of Harvard this is the continuation of a trend already revealed in the case of the contemporary fathers over their own fathers. Every thirty-two years at Cambridge add an inch in height and eight pounds in weight to the student average.

"The same forces operating in the Harvard stock Professor Boas years ago found at work among the children of the immigrant foreign-born in New York. Again there is room for debate whether the influence of better food, better housing and out-of-door exercise is more positive or negative; that is to say, whether a favorable environment actually stimulates changes in stature or removes hindrances toward full physical development.

"There is very good reason for believing that the difference in stature usually noted between a dominant and a subject race, as between Aryan and Dravidian in India, or between Manchu and Southern Chinese, is not entirely due to the fact that a taller race of invaders imposed their rule upon a physically inferior indigenous population. Along with the powers of Government the invader naturally asserted a prior claim on the best food in the country and on the greater amount of leisure and recreation, thus accentuating any existing differences between a tall ruling class and a medium-height subject class."

CARRYING COALS TO NEWCASTLE

The following editorial from the New York *Times* of May 14 tells of National variations of a well-known saying:

"There have been sayings in many languages to suggest the folly of carrying things to places where they are already to be found in profusion. The one in most common use is 'carrying coals to Newcastle.' But centuries before the coal mines of Newcastle were worked, there was an adage in Greek about carrying owls to Athens. In the orient it was transporting pepper to Hindustan or oil to the city of olives. In France it was selling shells to those who came from San Michel; in Denmark sending fir trees to Norway; and in London casting water into the Thames.

"To these has now been added 'oats to Scotland.' A year and more ago there was great alarm because there was a 'dumping' of German oats upon the Caledonian coasts. Now it is reported to be a superior brand of American oats that menaces the native product. But will the oats from our fields produce the same sort of keen intellectuality and thriftiness that the porridge of home-grown oats has given (or have given, for 'porridge' is plural in Scotland) to the Scot through generations?

"Sydney Smith should rise from his grave to protest against the importation of the American avena, however palatable. When the Scot sits over a dish of foreign oatmeal instead of standing with his back to the wall as his ancestors did with their porridge, or takes to the steel shaft for his golf club instead of the native hickory, one may well ask: 'Stands Scotland where it did?'"

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

SURGICAL CLINICS OF NORTH AMERICA. Vol. 11, No. 2, April, 1931. (Lahey Clinic Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, $16.00 net; paper, $12.00 net.

INTERNATIONAL STUDIES on the Relation between the Private and Official Practice of Medicine with Special Reference to the Prevention of Disease conducted for The Milbank Memorial Fund. By SIR ARTHUR NEWSHOLME, K.C.B., M.D. Volume I. Octavo of 248 pages. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $4.00.

CLINICAL DIAGNOSIS BY LABORATORY METHODS. A Working Manual of Clinical Pathology. By JAMES CAMPBELL TODD, Ph.B., M.D., & ARTHUR HAWLEY SANFORD, A.M., M.D. Seventh edition. Octavo of 765 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.00.

NUTRITION AND DIET IN HEALTH AND DISEASE. By JAMES S. MCLESTER, M.D. Second edition. Octavo of 891 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $8.50.

HANDBOOK OF PHYSIOLOGY. By W. D. HALLIBURTON, M.D., LL.D. & R. J. S. MCDOWALL, M.B., D.Sc., Nineteenth edition. Octavo of 842 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., 1930. Cloth, $4.75.

THE TREATMENT OF BEHAVIOR DISORDERS FOLLOWING ENCEPHALITIS. An experiment in re-education. By EARL D. BOND, M.D., and KENNETH E. APPEL, M.D. Octavo of 163 pages, illustrated. New York, The Commonwealth Fund Division of Publications, 1931. Cloth, $1.75.

THE HARVEY LECTURES. Delivered under the auspices of the Harvey Society of New York, Series 25, 1929-30. Octavo of 225 pages. Baltimore, Williams & Wilkins Co., 1931. Cloth, $4.00.

MEDICINE: An Historical Outline. By M. G. SEELIG, M.D. Second edition. 12mo of 205 pages, illustrated. Baltimore, Williams & Wilkins Co., 1931. Cloth, $3 00.

A MANUAL OF TUBERCULOSIS FOR NURSES. By E. ASHWORTH UNDERWOOD, M.A., B.Sc. 12mo of 272 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $2 50.

THE TREATMENT OF ASTHMA. By A. H. DOUTHWAITE, M.D., F.R.C.P. 12mo of 164 pages. New York, William Wood & Company, 1931 Cloth, $2.50.

PRACTICAL ANAESTHETICS for the Student and General Practitioner. By CHARLES F. HADFIELD, M.B.E., M.A. Second edition. Octavo of 336 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $3.50.

THE INTERNATIONAL MEDICAL ANNUAL: A Year Book of Treatment and Practitioner's Index. Editors: CAREY F. COOMBS, M.D., and A. RENDLE SHORT, M.D. Forty-ninth Year, 1931. Octavo of 551 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $6.00.

BACKACHE. By JAMES MENNELL, M.A., M.D. Octavo of 199 pages, illustrated. Philadelphia, P. Blakiston's Son & Co. Inc., 1931. Cloth, $3.00.

A SYNOPSIS OF THE UNITED STATES PHARMACOPOEIA AND NATIONAL FORMULRY PREPARATIONS. By H. J. FULLER, PH.C., PHM.B. Octavo of 247 pages. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $2.00.

RECENT ADVANCES IN CARDIOLOGY. By C. F. TERENCE EAST, M.A., M.D., and C. W. CURTIS BAIN, M.C., M.B. Second edition. Octavo of 353 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50. (The Recent Advances Series.)

SURGERY, ITS PRINCIPLES AND PRACTICE, for Students and Practitioners. By ASTLEY PASTON COOPER ASHHURST, A.B., M.D. Fourth edition. Octavo of 1189 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $10.00.

THE COMMON SENSE OF DRINKING. By RICHARD R. PEABODY. Octavo of 191 pages. Boston, Little, Brown, and Company, 1931. Cloth, $2.00.

COLLECTED PAPERS, 1904-1929. By EDWIN BEER, M.D. Octavo of 827 pages, illustrated. New York, Paul B. Hoeber, Inc., 1931. Cloth, $7.50.

WHITE HOUSE CONFERENCE 1930 ADDRESSES AND ABSTRACTS OF COMMITTEE REPORTS. White House Conference on Child Health and Protection called by President Hoover. Octavo of 365 pages. New York, The Century Company, 1931. Boards 50c.

THE VITAMINS. By H. C. SHERMAN and S. L. SMITH. Second edition. Octavo of 575 pages. New York, The Chemical Catalog Company, Inc., 1931. Cloth, $6.00. (American Chemical Society Monograph Series, No. 6.)

CRIPPLED CHILDRCN: Their Treatment and Orthopedic Nursing. By EARL D. MCBRIDE, B.S., M.D. Octavo of 280 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $3.50.

THE SCIENCE AND PRACTICE OF SURGERY. By W. H. C. ROMANIS, M.A., M.B., and PHILIP H. MITCHINER, M.D., M.S. Third edition. Two octavo volumes totaling 1868 pages, illustrated New York, William Wood & Company, 1930. Cloth, $12.00.

THE CRIMINAL, THE JUDGE, AND THE PUBLIC. A Psychological Analysis. By FRANZ ALEXANDER, M.D., and HUGO STAUB. Translated from the German by Gregory Zilboorg, M.D. 12mo of 238 pages. New York, The Macmillan Company, 1931. Cloth, $2.50.

THE DIAGNOSIS AND TREATMENT OF BRAIN TUMORS. By ERNEST SACHS, A.B., M.D. Quarto of 396 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $10.00.

PRACTICAL CLINICAL PSYCHIATRY, for Students and Practitioners. By EDWARD A. STRECKER, A.M., M.D., and FRANKLIN G. EBAUGH, A.B., M.D. Third edition. Octavo of 553 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $4.00.

BOOK REVIEWS

ORAL DISEASES: A Practical Treatise Offering Diagnostic and Therapeutic Aid to the Practitioner of Medicine and Dentistry. By JAMES J. ZEMSKY, D.D.S. Octavo of 402 pages, illustrated. Brooklyn, New York, Physicians and Surgeons Book Co., 1930. Cloth, $8.00.

"That he who runs may read" might sufficiently describe this book of 414 illustrations within 335 pages of terse reading matter. This volume it seems was definitely written for the busy practitioner so that by spending the least amount of time he might see and read of the many diseases encountered in the oral cavity. A book so complete in itself that there is nothing to be critical of, a book that reads so easily that it is pleasurable, a book so well printed and illustrated, that there is nothing left but to congratulate the author for having conceived it and to thank his publishers for the splendid production of so beautiful a volume.

LEONARD KOHN.

THE DRAMATIC IN SURGERY. By GORDON GORDON-TAYLOR, O.B.E., M.A., F.R.C.S. Octavo of 88 pages, illustrated. New York, William Wood and Company, 1930. Cloth, $4.00.

A small volume, intended to entertain rather than instruct. The author recounts the very numerous operations he has knowledge of or has himself performed, which, owing to their magnitude and to the displayed surgical skill, are unusually impressive thus bordering on the dramatic. Technical considerations are entirely omitted. The value of the book is historical only.

GEO. WEBB.

HANDBOOK OF THE VACCINE TREATMENT OF CHRONIC RHEUMATIC DISEASES. By H. WARREN CROWE, D.M., B.Ch., M.R.C.S. Octavo of 52 pages. London and New York, Oxford University Press, 1930. Boards, $.80. (Oxford Medical Publications.)

This brief monograph on a subject of universal interest leaves the reader in a contented state of mind. Here we have a method of treatment influencing all forms of chronic rheumatism in a *specific* manner by the use of *stock* vaccines. Admitting that changes are taking place in the treatment of these conditions they have not yet reached that stage of simplicity nor that degree of efficacy which the author records with such emphasis and assurance.

S. R. B.

TRAUMATOTHERAPY: The Treatment of the Injured. By JOHN J. MOORHEAD, B.Sc., M.D. Octavo of 574 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $7.00.

This new edition of "Traumatotherapy or Treatment of the Injured," by Dr. Moorhead, is most complete in all details of the treatment of traumatic surgery, and includes practically every traumatic injury from contusions to complicated fractures, besides containing special chapters on after care, also medico-legal and allied aspects as applied to traumatic wounds.

In reading this book it is clearly evident that the author has presented to the medical profession a systematic method of treatment from the knowledge which he has gained by personal application and long contact with this type of surgery. There are 625 illustrations which are very helpful to the reader. This volume should prove an interesting addition to the library of any physician engaged partly or wholly in the treatment of traumatic wounds.

RALPH F. HARLOE.

CANCER: Its Origin, Its Development and Its Self-Perpetuation. The therapy of operable and inoperable cancer in the light of a systemic conception of malignancy. A research. By WILLY MEYER, M.D. Octavo of 427 pages, illustrated. New York, Paul B. Hoeber, Inc., 1931. Cloth, $7.50.

The primary aim of the author in publishing in book form a series of articles, which have appeared in various medical journals, was to show that cancer is the expression of a systemic disturbance. This aim seems to be in accordance with the general opinion of today. This opinion succinctly expressed is that cancer is a local expression of a general poisoning, and that the removal of the cancer by any means leaves the causal factor or factors at play in the body, so that a new cancer develops or the same causal agencies express their activities in a different form. As far as the primary aim of the author was concerned he failed to present data to demonstrate his conception.

The author reviews cancer literature to a very large extent, and feels that a type of acidosis is the cause of cancer formation. The exact status which causes the acidosis is not brought out. Alkalosis is recommended as a method of combating the systemic cause. No adequate method of accomplishing this result is given.

The essential value of this book rests in its complete survey of cancer knowledge. The interest of the book wanes after the first few chapters, and it is in these chapters that the most significant information is to be found.

J. ARTHUR BUCHANAN.

ANAESTHESIA AND ANAESTHETICS. By F. S. ROOD, M.B., and H. N. WEBBER, M.A. Octavo of 292 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $4.50.

Simple, practical, individualistic—an English Flagg. Viewpoint, practice, apparatus necessarily trans-Atlantic. Queer how they like to issue books. We peg away, experiment and lead the way, and they tell us about it. The reviewer is going to write a book some day, and when he does it will be after the fashion of this one. He was delighted with the account of the work of these Londoners when he took his first dip into their book; he still likes it and better now that he has read it through carefully. It is not a dogmatic pronouncement but a personal revelation of how and why they came to learn what they now advise others to do. A carefully made index, just about enough illustrations (several rather oversize), a delightfully new arrangement of the subject matter, some lack in the newer methods and agents, maybe; but there you are, a well arranged, thoughtful narrative, properly illustrated and finely printed.

See how this is—Respiratory Aspects come first in 18 pages; Choice of Agents and Preliminary Medication, the same number; Preliminary Details, almost as many; A Typical Ether Case, 29 pages; Endo-Tracheal Insufflation, 16 pages; now notice—Chloroform, only 11 pages; Nitrous Oxid, 24; Ethyl Chloride, 10; Difficulties, 50 pages; the 40-odd pages given to injectional methods might have well been omitted or extended: Evans, Labat, deTakats and others have written books on that.

It can be seen easily that the book is intended for those who are relatively unused to the giving of anaesthetics. But we all can read it with profit. What with filtration methods, carbon dioxid stimulation, oxygen and CO_2 therapy and resuscitation, avertin and other agents, to say nothing of the encroachments of techni-

cians, we are all learners. Rood and Webber have written an attractive text-book. A. F. E.

THROUGH THE ALIMENTARY CANAL WITH GUN AND CAMERA: A Fascinating Trip to the Interior. By GEORGE S. CHAPPELL. 12mo of 231 pages, illustrated. New York, Frederick A. Stokes Company, 1930. Cloth, $2.00.

This book is not designed to teach science by the devices of personification, dialogue, travel and adventure. The author, a layman, uses his meager scientific knowledge as the excuse for vaudeville puns and funny page cartoons. The adventurer, for example, explores the mines in the Molar Mountains, and says that more gold is sunk in them than is ever extracted. Also St. Pancreas is identified as the Egyptian god, Osmosis, "the secretive one."

Never once is the medical profession mentioned. The humor of the book is always good natured and will be enjoyed by doctor as well as layman. F. O.

PHILOSOPHY OF A BIOLOGIST. By SIR LEONARD HILL, F.R.S. 12mo of 88 pages. London, Edward Arnold & Company: New York, Longmans Green & Company, 1930. Cloth, $1.40.

This little volume holds one's interest from the first to the last page. The author has expressed many ideas in so few pages. His deductions are quite plausible, many may not appeal to some of his readers, yet it surely will stimulate all to think. On page 50, there is a misprint, The Spinal-accessory nerve, instead of The Musculo-spiral nerve. GAETANO DE YOANNA.

THERAPEUTICS, MATERIA MEDICA AND PHARMACY: The Special Therapeutics of Diseases and Symptoms, the Physiological and Therapeutical Actions of Drugs, the Modern Materia Medica, Official and Practical Pharmacy, Prescription Writing, and Antidotal and Antagonistic Treatment of Poisoning. By SAM'L O. L. POTTER, A.M., M.D. Fifteenth edition, Revised by R. J. E. SCOTT, M.A., M.D. Octavo of 997 pages Philadelphia, P. Blakiston's Son & Company, Inc., 1931. Cloth, $8.50.

The general form of this edition remains the same as in previous ones, the early chapters giving a description of the constituents of drugs, their classification, methods of administration and dosage. The various drugs are arranged alphabetically, which is often a convenience. New material has been added and a number of the older prescriptions removed. The official preparations of the Materia Medica have been made to conform with the Tenth Revision of the United States Pharmacopoeia and the Fifth Edition of the National Formulary.

It is one of the good books on the subject and its arrangement is such that it is very convenient for quick reference. W. E. MCCOLLOM.

A TEXT-BOOK OF HYGIENE. By J. R. CURRIE, M.A., M.D. Octavo of 844 pages, illustrated. New York and Edinburgh, William Wood and Company, 1930. Cloth, $8.50.

This work covers the subject of sanitation very completely. It not only goes into detail from a general standpoint but covers each subject in a minute way.

We like the comprehensive treatment of each subject and the explicit way that it is covered.

It is definitely a text-book for students of sanitation and should be especially valuable to medical students. J. J. WITTMER.

CARE OF THE INFANT AND CHILD: A Book for Mothers and Nurses. By HARRY R. LITCHFIELD, M.D., and LEON H. DEMBO, M.D. Octavo of 138 pages, illustrated. Baltimore, Waverly Press, Inc., 1930.

This is a monograph of 132 pages written as a reference for mothers and nurses. It well serves the purpose for which the authors intended. The usual subject matter of the ever-increasing number of such books is taken up in orderly manner. T. B. G.

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. By Various Authors. (Prepared under the direction of the Medical Research Council.) Volume VII. Octavo of 509 pages. London, His Majesty's Stationery Office, 1930. Cloth, £8-8-0 a set; £1-1-0 each.

This volume is devoted to viruses, virus diseases and to bacteriophage. Probably in no other work in English is there such an exhaustive discussion of filterable viruses and the diseases they cause. About 450 pages are given to this subject. Each chapter is written by one with special experience in the subject. After discussing viruses and cell inclusions there are chapters on virus diseases of plants, insects and animals and then the long list of virus diseases in man, including smallpox, encephalitis, poliomyelitis, rabies, trachoma, measles, typhus, trench fever, Rocky Mountain spotted fever and the interesting group of filterable tumors and infectious anemia and leukemia.

The bacteriophage phenomenon is thoroughly discussed in the last 50 pages of the volume.

E. B. SMITH.

ABDOMINO-PELVIC DIAGNOSIS IN WOMEN. By ARTHUR JOHN WALSCHEID, M.D. Quarto of 1000 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $12.50.

The book written by Walscheid entitled "Abdomino-Pelvic Diagnosis in Women" is profusely illustrated with many original drawings, and consists of some 1,000 pages.

The book is very interesting reading and covers the subject fairly well. PHILIP OGINZ.

PRIMARY SYPHILIS IN THE FEMALE. By THOMAS ANWYL DAVIES, M.D. Octavo of 111 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $4.00. (Oxford Medical Publications.)

As will be noted from the title, the author has made an unusual contribution to the study of primary syphilis in the female. The book contains 104 pages covering detailed descriptions of luetic lesions occurring on the various external and internal genitalia together with their differential diagnosis. The author goes far in correcting erroneous teachings and writings to the effect that primary lesions are rare in the female or that the lesions are essentially different from those occurring in the male.

The work is based upon a case study of 3,972 female acquired cases at St. Thomas' Hospital of which 578 showed primary lesions with an incidence of 44% on the cervix. It is worthy of note that the spirochaeta were found in the majority of cases on the dark field test. This indicates the great step forward in the early diagnosis of lues and the greater incidence of cure resulting from treatment in this stage.

The various lesions are vividly illustrated by colored photographs.

The author pays tribute to the success of the venereal clinics under the Ministry of Health in showing that the incidence of fresh cases in England and Wales from 1921 to 1927 was reduced 50%.

Practitioner and specialist alike would do well to review this book. AUGUSTUS HARRIS.

SURGICAL EMERGENCIES IN PRACTICE. By W. H. C ROMANIS, M.A., M.B., and PHILIP H. MITCHINER, M.D., M.S. Octavo of 608 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $6.00.

A book written by experienced surgeons for beginners in the craft. Well planned, lucidly written, adequately illustrated and thoroughly up to date. The volume fills a gap in surgical literature and will be welcomed by every house-surgeon. GEO. WEBB.

OUR NEIGHBORS

ANNUAL MEETING IN TENNESSEE

The May Journal of the Tennessee State Medical Association contains the following editorial on the annual meeting which was held April 14-16 in Knoxville:—

"In many respects the recent meeting of the Tennessee State Medical Association held at Knoxville was one of the most successful the Association has ever experienced. It is starting off the second century of its existence in a glorious way. Four hundred and fifty-five doctors registered. There were fifty of the sixty-seven component societies represented.

"Only one number was absent (from the scientific program); this was due to the death of the essayist, Dr. E. B. Bowery, of Johnson City. This is a most creditable showing for the men who were given places on the program. A vast majority of those listed to discuss the papers were present. Papers as a whole were exceptionally good. A wide variety of subjects was discussed. Regardless of one's particular interest or specialty in medicine, there were numbers on the program of interest. The attendance on the scientific sessions was good.

"The Knox County Medical Society did an exceptionally fine job as host of the meeting. It took work and it took money for the members of the Knox County profession to entertain the Association as we were entertained at Knoxville. Those committees are entitled to a great deal of credit for a lot of hard work.

"The only unfortunate incident was the fact that all in attendance at the banquet could not be seated, but this was not the fault of the committee on arrangemens, nor of the hotel. It was due to the fact that one hundred men presented themselves for plates at the banquet who had not registered at the desk. There are few institutions that can accommodate one hundred people who are not expected at a banquet and who fail to buy tickets beforehand.

"The House of Delegates did some very important work. Of first importance was the passage of an amendment to the by-laws creating a Liaison Committee with a membership of five. This committee has very important duties to perform in the maintenance of that state of harmony which should exist between health departments and the medical profession.

The Liaison Committee was described in an editorial in the May issue of the Tennessee Journal as follows:

"In 1928 the chairman of the Committee on Public Health recommended the creation of a Liaison Committee. The committee used the following language:

"'Your Committee further finds there is no official means of approach between the health agencies of the State and the State Medical Society. The president, vice-president, secretary, nor even the councilors, have authority to speak for the organized profession; and in view of this condition, we would therefore recommend that the House of Delegates create a liaison committee composed of three representative men, one from each grand division of the States, clothed with the authority to council with the health agencies and speak with authority for the State Medical Association upon any subject of Public Health and Preventive Medicine, which alike concern the public health agencies and the profession as a whole, especially policies and practice in the State's endeavor to control contagious and communicable diseases to the end that there may be maintained a mutual understanding and a cooperation between the two in handling the questions which are getting so much attention from the people as a whole.'"

CALIFORNIA JOURNAL TWENTY-FIVE YEARS AGO

California and Western Medicine, like the NEW YORK STATE JOURNAL OF MEDICINE, has a column of quotations from its issue of twenty-five years ago. The present May number contains the following editorial introduction to the quarter century quotations:

"On April 1, 1906, the great San Francisco Catastrophe took place. In the great fire which devastated the city, the office of the *California State Journal of Medicine*, the official publication of the Medical Society of the State of California, was burned to the ground. The May issue of the *California State Journal of Medicine* became a simple four-page leaflet without a single advertisement, which was gotten out under great stress and strain at a printing office at Oakland, by the late Dr. Philip Mills Jones, founder of the State journal and the then editor. The excerpts which appear in this month's Twenty-five Years Ago column are taken from this little four-page leaflet."

(*Continued on page 790—adv. xii*)

CORRECTING AN ERROR

In the Journal of the A. M. A., March 28th, 1931, page 30, we inadvertently stated the iron content of Mead's Cereal to be 68 milligrams per hundred grams. (This figure was confused with .0068 gms. iron per ounce.)

The correct content is 24 mgs. iron per 100 gms. But even so, Mead's Cereal contains —

26% more food iron than kidney
73% more food iron than spleen
100% more food iron than romain
172% more food iron than liver
179% more food iron than egg yolk

These five foods are compared because they are considered highest in food iron. (Mead's Cereal contains 100 times as much iron as whole milk.)

A well-known pediatrician has drawn attention to the fact that in practice, Mead's Cereal is more palatable and more readily taken by children than other iron-containing foods, some of which are quite unappetizing and even repellent, especially after long-continued use.

Mead Johnson & Co. SPECIALISTS IN INFANT DIET MATERIALS Evansville, Ind.

Mead's Cereal also is rich in copper, calcium, phosphorus and in other essential minerals.

(*Continued from page 788*)

The California Journal of May, 1906, contained the following editorial greeting:

"A Sad Greeting:—It was a very different sort of May issue we had planned. But, as all the world now knows, our beautiful city of San Francisco has been almost wiped out of existence. The editor has been able to confer with but one member of the Publication Committee and a few of the delegates living in Oakland, and these have authorized the bringing out of this number in its present form. There is not a business house of any sort left standing in San Francisco—no paper house and no printer—so this number is printed in Oakland. The mailing list of the Journal has also vanished, so that many exchanges and subscribers will not at once receive this issue. However, enough copies will be printed to supply all regular recipients in the course of time. Correspondents are respectfully warned, however, that their letters may not be answered immediately, for almost all typewriters have been destroyed and the whereabouts of our stenographer is an unknown quantity."

The annual meeting of the Medical Society of the State of California was in session when the earthquake occurred, and was described in the May, 1906, Journal as follows:

"Undoubtedly the annual meeting of the Medical Society of the State of California for 1906—its semicentennial—will remain forever the one most generally remembered. The registration book unfortunately is not at hand—one can only say that it once existed—but it is known that about 4 P. M. on Tuesday, April 17, the first day of the session, nearly three hundred members had registered. The program was unusually good; at least one copy is known to exist, and there may be others.

"Everything promised an unusually harmonious and profitable meeting. Unfortunately our plans were not well adapted to those of the remainder of the universe. At 5:14:48 on the morning of the 18th, the city was wrecked by an earthquake which lasted but forty-eight seconds. This, to those in other places, is now but ancient history, but to those of us who went through that and all the following days of horror, it will never become ancient. Fire broke out in unnumbered places immediately after the shock, and as nearly all the water supply mains had been broken, what the shock began the fire completed.

"Shortly after 9.30 A. M. on Wednesday, the president, Dr. R. F. Rooney, the secretary, Dr. Philip Mills Jones, and Drs. James H. Parkinson and H. Bert Ellis gathered on the steps of the wrecked Y. M. C. A. building and declared the society adjourn *sine die*. The secretary made

(*Continued on page 791—adv. xiii*)

(Continued from page 790—adv. xii)

three trips to the Association office, on the third floor, and saved the account books, minutes of the Council and minutes of the House of Delegates, together with some miscellaneous papers hastily gathered together. All advertising contracts, current vouchers, etc., are in a safe deposit vault, perfectly intact. When, or where the next meeting of the society will be held, no one knows; probably a meeting of the delegates will be called in due time. Even the whereabouts of the president, Dr. Rooney, is unknown to the secretary."

BASIC SCIENCE LAW IN OREGON

The May number of *Northwest Medicine* contains the following editorial on the manner in which the Basic Science Bill was received by the Legislature of Oregon:—

"In order to place a check on licensing practitioners of inadequate medical education and deficient qualifications, the basic science law has been established in a number of States, as a result of which there has been an immediate and striking reduction in the number of objectionable irregulars who have hitherto been licensed in large numbers by their respective examining boards. An attempt has been made at several sessions of the Oregon Legislature to enact such a law. While these have failed in the past, it was believed that the effort would be successful at the legislative session of last winter. A committee of leading practitioners from many cities of the State worked zealously in preparation for such legislative action. A physician was elected to the Senate and two to the House, who were appointed on their respective committees dealing with medical affairs.

"The contest on this bill centered in the Senate Committee on Medicine, Pharmacy and Dentistry. A Portland senator, who is an optometrist and optician with a fixed antipathy against the medical profession, was a member of this committee. Apparently his chief purpose was to block this bill. It had a stormy existence both in committee and before the Senate by reason of the activities of this man and other antimedical sympathizers. When it finally reached the floor of the Senate a prolonged and exciting controversy ensued. The leading opponent of the measure with vindictive vituperation assailed the medical profession, alleging many mendacious charges which, however, were successfully met and disproven by Dr. Booth, the medical senator. While the bill had been presented for passage as a majority report from the committee, the optometrist senator succeeded in getting his minority report for disapproval before the Senate for

Collosol
MANGANESE
CROOKES

MANGANESE is one of the inorganic elements recommended for many years for blood regeneration and for the treatment of coccogenic affections, particularly Furunculosis, Boils, Acne, etc.

COLLOSOL MANGANESE 1-400 is extremely stable and does not precipitate on addition to the blood plasma.

Ampoules for intramuscular injection.

It is safe to inject and is almost totally free from the pain and discomfort attendant on the injection of solutions of manganese salts.

COLLOSOL MANGANESE is most successfully used intramuscularly, although some observers report favorable results from hypodermic injection. It has also a growing acceptance for oral use.

Vials for oral administration.

WOMAN'S AUXILIARY IN THE NORTH CENTRAL STATES

An outline of the Woman's Auxiliary in the Eastern States was abstracted on page 310 of this Journal of March first. The Auxiliary in the North Central States is described in the following abstract from the April issue of the *Journal of the Iowa State Medical Society*:

"From Indiana we know we are to have constructive work during this year. Physicians as a class are not prone to participate in legislative matters, but when four distinctly separate bills, which affect the profession directly are presented during one session of a State's Legislature, it is time to be up and doing. The Indiana Journal never fails to give the Auxiliary space, and it is little wonder the Indiana women are up and coming when they have such editorial notes to enlighten and guide them in their constructive program work, as one finds in this same Journal.

"Kansas is slowly getting a few things accomplished. A world-wide depression has rendered prophets quite fameless abroad as well as at home, but the doctor's wife in Kansas is coming into her own, and we prophesy that the Auxiliary will climb to the top due to the indomitable spirit of the leaders in that state.

"In Illinois the motto might well read, 'Builders we are, and builders we must ever be. Builders, not in stone that shelters life, but builders in life.' We find good constructive programs of well-balanced educational value, we find a journal ever ready to broadcast Auxiliary news, and, best of all, we find a healthy organization line-up and an advisory board from their Medical Society. Several of their County groups are having their members get busy with the 'Health Audit Program.' One project worthy of mention comes from Vermillion County on the eastern boundary of the state. The County Auxiliary put on the Health Institute in Danville last November. A member from every agency in the County working out any kind of a health program was included in the personnel of the speakers.

"Wisconsin, Iowa and South Dakota are among the latest States to join the National Auxiliary. Organization is the keynote for their work, and the National Study envelopes are offered as program material.

"Montana and North Dakota are debating pro and con, but as Mrs. Hoxie said in her Detroit report, 'I believe it will be a mistake from now on to organize a new state auxiliary unless it appears reasonably certain that there is interest enough among the doctors who want the auxiliary, so they will foster it and

(Continued on page 795—adv. xvii)

(Continued from page 794—adv. xvi)

stand back of it.' And so we leave Montana half-hearted about forming an auxiliary, and North Dakota in the air.

"We find Michigan giving intelligent co-operation with state and county officials. Women, like men, are interested in the improvement of civic affairs and healthful living and are realizing that they need to be armed with a definite knowledge of health laws and public health practices.

"Missouri is in a very healthy condition. We find that Mrs. A. B. McGlothan, the President-elect of the Woman's Auxiliary to the American Medical Association, attended President Hoover's White House Conference for Child Health and Protection, held in Washington, D. C., February 19 to 21.

"Mrs. A. W. McAlester tells us the women of Missouri are finding the study envelopes, published by the Education Committee of the Woman's Auxiliary to the American Medical Association, most interesting and instructive.

"Minnesota, the North Star State, has had a busy and successful year in organization. The President and Organization Chairman have visited over the state and planned meetings and educational programs with many County groups. In October the International Medical Assembly met in Minneapolis, and at this time the Hennepin County Auxiliary celebrated its twentieth anniversary by being hostess for five days to the visiting doctors' wives.

"Hennepin County is having a year with a definite program. Each month a speaker is scheduled, and one meeting during the year is reciprocity day and each Auxiliary in the state is invited to send visitors. This group features philanthropic work for tuberculosis patients at Glen Lake and do much for the library at the Sanatorium. They have helped the Medical Society furnish their library and club rooms, spending $1,000."

THE STATE JOURNAL OF NEW JERSEY

Which State Medical Journal is the best, and why? This question is answered in the May issue of the *Journal of the Medical Society of New Jersey* in which the editor says in his annual report:

"In 1924 the *Journal of the Medical Society of New Jersey* was practically a replica of all other state medical society journals; that is to say, it regularly consisted of about 6 sections, or departments, covering original articles, editorials, an occasional special article or case report, county society reports, obituaries and news items. The

When decalcification occurs during pregnancy

IT IS important to warn expectant mothers of the danger of calcium deficiency during pregnancy. For unless there is sufficient calcium to take care of the developing *foetus*, there will be a *withdrawal of calcium from the maternal structures* —resulting, among other things, in rickets, soft bones, and carious teeth.

During this period Cocomalt is highly valuable for two reasons: It contains Vitamin D which mobilizes calcium, and it is mixed with milk which in itself is an essential source of calcium.

Recommend this delicious chocolate flavor food drink to expectant mothers. Not only does it contain Vitamin D—not only does it add 70% more nourishment to milk—not only is it tempting to finicky appetites—*it supplies extra body-building proteins, carbohydrates and minerals so essential to the mother and to the coming child.*

Recommend Cocomalt to your young patients, too. They'll love it. Cocomalt is high in concentrated food value—low in cost. At grocers and leading drug stores—½ lb., 1 lb., and 5 lb., family or hospital size.

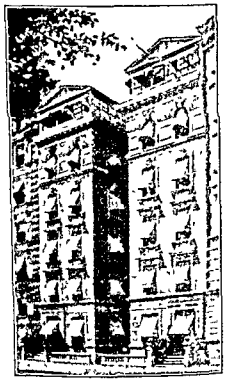
COUNTY SOCIETY REPORTS IN MISSISSIPPI

The *New Orleans Medical and Surgical Journal* is the organ of the Louisiana State Medical Society and the Mississippi State Medical Association. The April issue contains the following appeal from the editors of the Mississippi section to the County Societies to report their activities more fully:

"Your editors for Mississippi have sent to each President of our County Medical Societies the following letter, which is self-explanatory:

"'A real journal means a great deal in the success of a medical society. Aside from the publication of scientific papers, one of its chief functions is to stimulate interest in the society and to keep the members in touch with each other and with their various activities. To do this effectively it is necessary to have notes of what is going on in every part of the State in every issue.



"'Three men chosen by the State Association cannot cover the State each month alone. To remedy this defect and to make the official journal of the Mississippi State Medical Association really worth while to the Association and to every member of every County Society, we are forming a Board of County Editors, this Board to be appointed by the presidents of the various County Societies.

"'The duties of the county editors will be to send in to the editors once a month all the news of the doctors and their families in their own counties. This does not let out the presidents and secretaries from furnishing reports of meetings of the societies. Our best material has come from presidents and secretaries. It is an effort to divide up the work and to cover more territory with greater efficiency.

"'Will you not now appoint an editor for your society, picking a man who will really take the appointment seriously and do something, and send to me his name and address so that I may get in touch with him personally? I would also like to publish the names in the next issue of the *New Orleans Medical and Surgical Journal.* (See Editorial on page 768.)

"'We thank you for your cooperation and assuring you of our earnest desire to make your Journal of the greatest interest to you and to your members.'"

For Alcoholism and Drug Addiction

Provides a definite elimination treatment which obliterates craving for alcohol and drugs, including the various groups of hypnotics and sedatives.

Physicians are invited to be in attendance on their patients. Complete bedside histories are kept.

Department of physical therapy and well equipped gymnasium. Located directly across from Central Park in one of New York's best residential sections.

Any physician having an addict problem is invited to write for "Hospital Treatment for Alcohol and Drug Addiction"

CRIPPLED CHILDREN'S CARE IN KANSAS

The May Journal of the Kansas Medical Society contains the following editorial description of the new law relating to the care of crippled children:—

"The provisions of the law are unusually thorough and seem to provide for every contingency that may arise in this problem. It has a remarkably broad interpretation of the meaning of the crippled child, embracing all persons under twenty-one who have a physical defect or disease that can be improved or removed by appropriate medical or surgical treatment. It provides the finances to defray the expense of such treatment, each county being assessed one-tenth mill for every taxable dollar to comprise a separate fund to be used only for the care of crippled children of that county. It includes compensation to the doctor as well as to the hospital. It provides for a commissioner to carry out the provisions of the law and to see that the afflicted child gets into the hands of none but competent specialists and in only those institutions that have fully adequate facilities to give the best service. It also provides safeguards so that only deserving indigent children may reap the benefits of this law. Furthermore, it opens the way for the care of such patients in various sections of the State as soon as adequate facilities and competent personnel become available.

"It is estimated that over 5,000 children will become eligible for this treatment. Yet there is no well-organized children's hospital in the entire State that can provide the variety of services such as can be secured in some of our neighboring States. There is at the hospital of the State medical school a children's ward with a maximum capacity of fifty patients and a similar ward in only one other hospital in the State. There should be a well equipped, specially designed children's hospital with at least three times as many beds, including a brace shop, a complete physiotherapy unit, a department of occupational therapy and a special school for the education of patients who may be kept months from school. Only with such supplementary departments and equipment can the hospital be thoroughly efficient, but this is necessarily expensive and can be erected and managed most economically where an organization of well-qualified specialists already exists, such as in the medical schools of the State universities. The States of Oklahoma, Minnesota, Wisconsin, Iowa, and Inliana have provided such children's units at their respective medical schools and the medical profession should urge that Kansas do the same with its medical school.

"Failure of the law may result from inadequate facilities rather than from the law itself or the attitude of the doctors, and all physicians should be informed of this situation and use their influence to change this lack of preparedness. The medical profession should not only be awake to the opportunities of this law but should be cognizant of the danger to this law if a few improperly qualified physicians should succeed in using the law to further their own private interests or if the cultists should succeed in their endeavors to be permitted to carry on their unrecognized practices on children under the protection of this law.

"Two obligations rest upon every physician interested in his community and in the crippled children of the State, first, to give unstinting support to the crippled children's commission in limiting the care of their wards to only those organizations that are adequately equipped and have competent specialists on their staffs; and, second, to use every influence to secure more adequate and larger facilities for such care, either at the State medical school or at some other large center or at several places."

PYODERMA GANGRENOSUM

By LEE McCARTHY, M. D., and RUSSELL FIELDS, M. D., WASHINGTON, D. C.

DURING recent years there have been occasional reports in the literature by surgeons and dermatologists, as well as pathologists, of gangrenous ulceration of the skin following some chronic, debilitating infectious process of long duration. Such a case report with comments is presented herewith.

Patient, a white, unmarried, twenty-eight year old woman, was admitted to Garfield Hospital on August 18, 1930.

Chief Complaint—skin trouble and diarrhoea.

Family history entirely negative.

Past illness began with diarrhoea eight years ago that was accompanied by fainting spells. Patient thought she had summer diarrhoea and paid little attention to it, although she had blood and mucus in her stools and as many as twenty-five movements in a day. These attacks have lasted for one month or more every year since that time. She was able to be up and about during these attacks until three years ago. In June, 1928, she had an appendocostomy performed in Richmond and was discharged shortly after as considerably improved. One year ago a colostomy was done in Garfield Hospital and she was once more discharged shortly after as improved. Aside from the usual diseases of childhood there is no other history or chronic infection. The patient has never lived in the tropics or further south than Richmond.

Present illness began in March, 1930. The patient started by having ten or twelve stools daily accompanied by pain in the left lumbar region. The stools were yellowish brown, with no visible blood, but considerable mucus was present. She was treated at that time with vaccines and local applications with no appreciable result. Three weeks after the beginning of this attack, the skin was involved for the first time in the form of a small boil on the middle of the forehead. This boil broke down in the center and the ulcer thus formed gradually enlarged until practically the entire forehead was involved. In June, 1930, a similar area of ulceration appeared on the right side of the face and neck. Since that time the patient's general condition has become worse and worse and she has been confined to her bed or room continuously.

Physical Examination: On August 15th, by Dr. Fields. Head and Neck Region: The entire forehead was covered by a thick, brownish-gray crust beneath which was an extensive area of ulceration. The neck on the right side showed an area of ulceration running medially to the midline and posteriorly to the hair line in the occipital region. This lesion extended upward in the form of a band one-half inch in width just anterior to the ear as far as the hair line. In a downward direction this same band extended to the clavicle. The edges of the ulcerated areas presented a bluish, boggy appearance and were extensively undermined for a distance of one to two centimeters. Pressure along the edges brought forth a considerable amount of gelatinous pus. The base of the ulceration is covered with a moist type of pus and considerable tissue debris. A profusion of granulation tissue can be seen on the edges of the ulceration where the activity is the greatest. The mucous membranes of the mouth were pale and the tonsils appeared to be somewhat enlarged. Examination of the lungs, heart and abdomen were essentially negative. A herniated scar in the right inguinal region is noted. There is no ulceration in this area. The reflexes are normal.

Laboratory examination by Dr. Lindsay on August 19, 1930, showed the Wassermann was negative. Haemoglobin was thirty-two per cent, with 2,000,000 red blood cells and 10,000 white blood cells, of which seventy-five per cent were polymorphonuclears, twenty per cent lymphocytes and four per cent eosinophiles. The urine showed a trace of albumen with a few white blood cells and epithelial cells. The blood showed a total NPN forty-six milligrams, sugar one hundred milligrams, and chlorides five hundred milligrams. A staphylococcus albus and a hemolyticus streptococcus were found in the

stools and in the pus from the skin. About this time three blood cultures were negative. Examination for entamoeba histolytica both in the stools and in the pus from the skin were negative on several occasions. On October 15th, the compliment fixation test for amoeba by Col. Craig, at Walter Reed Hospital, was one plus, which is considered a negative reading in the absence of amoeba. However such a finding should cause further search to be made for amoeba. On the 16th of October the stools showed a pure culture of staphylococcus albus. The hemolytic strep-

Figure 1

Note extensive ulceration with production of hypertrophic granulations in the vicinity of the undermined edges. (*Nov.* 1, 1930.)

tococcus and the staphylococcus albus have been isolated repeatedly from the bowel and skin. The biopsy from the skin showed a chronic inflammatory process that resulted in a deep ulceration of the skin. The edges were markedly undermined No amoebae were found in any of the stained sections Many cocci were seen deep in the tissue below the ulceration.

On the 17th of October the protoscopic examination by Dr Warfield resulted as follows: Finger enters without obstruction but with pain Sphincter good tone. Consistency thick and granular. Instrument enters with considerable pain, but with no obstruction. Patient unable to get in exact knee chest position due to pain in neck. Mucosa red, edematous, granular. No actual ulceration. Culture taken from exudate. The oozing of blood was not local, but general. There were several small whitish areas in the mucosa. Anal region showed some bluish veins.

The *x*-ray examination of the chest on the same date shows no evidence of abnormality. The stomach and duodenal cap are normal There is ulcerative colitis involving the entire left colon distal to the hepatic flexure. There is no evidence of apical abscesses about the teeth. In other words this patient showed secondary anaemia, ulceration of the skin and chronic ulcerative colitis.

Progress of the Case. On the first admission the patient remained in Garfield Hospital eleven days. She left the hospital for one week and returned again on September 2nd and has been there continuously. Her temperature has ranged from ninety-eight to one hundred and one, her pulse from eighty to one hundred and ten, and she has been having from ten to twenty-five stools per day. Naturally with this great depletion, the patient's condition has become very bad indeed. She has been given transfusions on September third and October twenty-ninth and is to have another one this week. Her general condition was particularly improved after these transfusions. On the twentieth of October her haemoglobin had come up to forty-eight per cent, with 2,400,000 red blood cells, while on the twentieth of November the haemoglobin was fifty per cent and there were 3,400,000 red blood cells, and only 8,000 white blood cells. During the month of October and the first two weeks in November the patient was given liver with no noticeable improvement. On November fifteenth we started giving "Stovarsol," one-half a tablet daily. This brought the stools down to twelve daily. The patient is now getting one full tablet a day for a week and then a period of rest for a week. The last accurate count of the stools during twenty-four hours showed the number to be twelve. Despite this the patient has gained six pounds in weight in the last month.

The ulcerated area of the skin gradually enlarged day by day; on certain days new skin was undermined for a distance of one to two centimeters. The lesions all kept their serpiginous configuration and the undermined edges showed the bluish gray, boggy appearance noted above. The advancing edge was always preceded by an inflamed zone about one centimeter in width On October first, six weeks after admission, the patient was very bad and she was having about twenty-five bloody, mucous stools daily At this time the skin lesion had almost doubled its original size as seen on admission, and a new oval shaped lesion about four by nine centimeters in size had appeared on the anterior surface of

the neck. This was a new lesion and was not an extension from the older one. It was interesting to watch the formation and development of this new lesion. After a week of increased bowel activity, when the patient's condition appeared the worst, a crop of small discrete pustules surrounded by an inflammatory zone appeared on the neck. In four or five days the pustules softened, ruptured and the small ulcerations with bluish, boggy, undermined edges united to form a larger ulceration similar to those already present. A similar pustule formed on the left arm at the site of a veinous puncture.

At this time Stovarsol and liver extract were given internally and the fistulous tracts in the undermined portions of the skin lesion were opened up by wide incision. Continuous wet dressings of one-quarter to one per cent copper sulphate solution were applied to all lesions. Although the dressings caused considerable pain, in the course of a week a marked improvement was noted in all the ulcerated areas—the spreading edges disappeared and the lesions were healing rapidly from the borders inward. Healing occurred by the production of epithelial sprouts from the edges. The resulting scar is very thin, atrophic and pigmented a deep brown. The appearance is quite similar to that of an old tuberoserpiginous syphilis with its pigmentation and serpiginous configuration. At the same time the patient's general condition had greatly improved.

At the present time the ulcerations have been reduced to one-quarter their original size and the patient's general condition is much improved. Transfusions seemed to be of the most therapeutic value. Dyes, vaccines, bacteriophages locally or intravenously, sodium and potassium tartrate, foreign proteid therapy in the form of small doses of typhoid vaccine, *x*-ray, et cetera, were not tried as all these had been shown to be of no avail in a report of five similar cases from the Mayo clinic.

Differential Diagnosis: Such lesions as those of bromoderma, tertiary syphilis, blastomycosis, tuberculosis, sporotrichosis and coccidiodial granuloma are very similar to this type of ulceration especially when it is covered with crusts. The history of the case and the use of the pathological laboratory with particular attention to the biopsy ruled out all these diseases. The only other ulceration of a similar nature is that termed amebiasis cutis and our studies so far have failed to find any parasite of the entamoeba histolytica group.

Prognosis: Judging from the reports in the literature of the past fifteen years, most of these cases undergo periods of marked exacerbations and remission with a fatal termination after the patients have become completely debilitated by the infectious process. Recently however, Brunstring of the Mayo clinic has reported five cases in which the skin lesions were entirely healed and the bowel condition was quiescent. If the improvement in our patient continues, we may hope for a similar favorable result as far as the skin condition is concerned. Of course the patient, if she does get well, will always have loose bowel movements due to the scarring of the bowel wall and loss of power of absorption of fluid on account of this scarring.

Comment: In going over the cases reported in the literature we have found two great groups exist. The first group comprises those cases in which the entamoeba histolytica could be demonstrated in the stools and in the skin either as the motile organism from the pus or as the fixed parasite in the stained section. The second group comprises cases in which the haemolytic streptococcus and a staphylococcus albus have been regularly and repeatedly found. Common to both groups is the fact that the skin ulcerations have

Figure 2
Later photograph to show beginning of healing of lesion on forehead.

invariably been preceded by a serious infection of several months' or years' duration. Most commonly the infection has been a chronic ulcerative colitis and less often an empyema. During the progress of the disease it was invariably noted that there was a direct parallel relationship between the behavior of the skin lesions and the underlying debilitating condition; when the general condition and the colitis improved, the skin lesions often healed completely, only to break down again with a recurrence of the bowel disturbance. Exacerbations and remissions have been the rule in these cases.

In the group due to the entamoeba, the skin

ulcerations have followed some operative procedure which established a connection between an infected internal organ and the skin. Operations for removal of gall stones, the appendix or hemorrhoids, have been followed by skin ulcerations due to the entamoeba at the site of incision, while one case is on record of ulcerations on the chest following drainage of an empyema due to a liver abscess rupturing in the pleural cavity. There has been considerable doubt as to whether the entamoeba histolytica was the actual cause of the bowel and skin condition. In a recent paper read before the dermatological section of the Southern Medical Association, Engman and

Figure 3

Appearance of the large lesion on the right side of neck March, 1931, when discharged from hospital.

Meleney demonstrated beyond a doubt that the entamoeba was the true etiological agent in their cases.

SUMMARY

1. We have described a case of chronic ulcerative colitis of eight years duration that was complicated eight months ago by the appearance of an unusual type of ulceration of the skin. We believe that the gangrenous pyoderma is only a part of a generalized infection that results in a marked lowering of body resistance which in itself permits invasion of the skin by the causitive organisms. Attention is called to the fact that ulcerations did not occur in regions where operative procedure established a union between the bowel and the skin.

2. Amoebae were not found in the skin or intestines, and it is believed that we are dealing here with a staphylococcus albus and a hemolytic streptococcus acting in symbiosis as the causitive agents.

3. Transfusions, Stovarsol by mouth, and local applications of one per cent solution of copper sulphate have given the best therapeutic results.

STUDIES IN INTESTINAL INTOXICATION III

Improved Vaccine Therapy in Intestinal Intoxication and Chronic Focal Infection

By CLARENCE W. LIEB, M.D., NEW YORK, N. Y.

PHYSICIANS who have used "autogenous" or stock vaccines in the treatment of intestinal intoxication or chronic focal infection have reported extremely variable results. Many of them are very enthusiastic, while quite as many feel that vaccines have doubtful value.

My experience indicates that most of the failures have been due to improper composition and preparation of the vaccines used or to faulty administration. The object of this paper is to show that, with better methods of selecting bacteria and by better control of the dosage both as to amount and interval the proportion of good results can be greatly increased. It is not intended that vaccines should be used as a sole measure for treating all types of infection or intoxication but that they be used in combination with other measures. In many cases, vaccines alone will effect a cure. In others it is necessary to augment the treatment with appropriate measures.

In spite of the excellent work of Crowe (1, 2, 3 and 4) in demonstrating that, for example, in arthritis vaccines can be used to great advantage, there is still persistent opposition to the use of this form of treatment. Because many of his claims have been confirmed by the use of our new methods, with even better results, not only in patients with arthritis, but also with a large number of other types of chronic focal infection or intoxication, it was felt desirable to report experience with the application of the more precise methods of selecting bacteria which Chapman outlines in his paper.

Intestinal and Other Foci: Focal infections or intoxications of the gastro-intestinal tract are intimately associated with foci in other areas, so that, while conditions in which the outstanding clinical symptoms, referable to the gastro-intestinal tract, were being treated with vaccines prepared according to our directions, it was found that distant foci were often greatly improved or completely cured. Quite often the primary focus was in the gastro-intestinal tract or, as a result of the absorption of toxins from this source, the general resistance was lowered and this paved the way for the invasion of distant foci by other bacteria. In these cases, successful treatment of the intestinal focus was followed by improvement in the distant foci. Who has not noticed the beneficial effects of colonic therapy on the progress of many cases of hypertension, diabetes, mental disease, skin lesions or arthritis? On account of this intimate association, we found it extremely difficult to confine our studies strictly to the gastro-intestinal tract. It was often tempting, while treating a patient for an intestinal complaint associated e.g., with psoriasis, to digress from his intestinal symptoms and watch the effect of the vaccine on his skin lesion. Consequently, many patients, who were referred to me for gastro-intestinal complaints and who were given vaccine therapy found that the vaccine also had a beneficial effect on their other symptoms. It became necessary, therefore, to treat a focal infection of the gastro-intestinal tract as a manifestation of tissue injury in one or several widely different parts of the body rather than to consider it as purely a disease of the intestinal tract.

Dilutions Used: We prepared our vaccines in six dilutions ranging from ten thousand per cc up to ten billions per cc. This series enabled us to confine the total volume injected to less than one cc by using a proportionate amount of the next higher dilution as soon as the amount given became too large. The unheated bacteria were suspended in 1.0 per cent phenol-saline and diluted with 0.5 per cent phenol-saline. Heating a vaccine was found to destroy much of its antigenic content and to increase its non-specificity. Our experience indicates that our unheated vaccines are much more potent therapeutically than heated ones so that it is necessary to use a much smaller initial dose than would be the case if ordinary vaccines were used and, by preparing serial dilutions, it is possible to increase the dose to a much larger amount than would be possible if the vaccine were limited to one dilution. This insures the possibility of a greater degree of immunization.

Effects of Vascularization: Where the focus is richly supplied with blood, the response to vaccine therapy should be prompt. If, on the other hand, the focal blood supply is poor, the beneficial effects will appear more slowly. The majority of chronic focal infections are due to a previous acute infection which has been followed by the production of an insufficient amount of antibodies to completely extinguish the infection. A small concentration of antibodies persists and this is sufficient to prevent an acute exacerbation unless the resistance is again lowered by exposure, vitamin deficiency, fatigue or other factors. If the focal antibody production becomes negligible, a state of hypersensitiveness persists and, under these conditions, a vaccine dosage of less than 100 bacteria will sometimes induce unfavorable symptoms.

Hypersensitiveness: It will be remembered that, when proteins are introduced into the intestinal tract, they are hydrolyzed into amino acids. These acids are absorbed through the intestinal

mucous membranes and synthesized into native proteins. If the mucous membranes allow unmodified proteins to penetrate, these proteins will produce the same effect as if they were introduced parenterally. Symptoms of protein shock or allergy may result from an infected respiratory or intestinal mucous membrane because infection modifies the differential function of these membranes. Air-borne proteins are likely to produce protein shock by penetration of the respiratory mucous membranes, while food proteins may produce intestinal distress from passing unchanged through the intestinal mucous membrane. In hypersensitive cases it is absolutely essential to inject only a very minute amount of the specific bacterial protein in the form of a vaccine, or the trace of existing focal antibodies will be overneutralized and the focus will be supplied with an excess of bacterial toxin and an acute exacerbation will result. The introduction of still larger amounts will only lead to severe reactions. Where hypersensitiveness is suspected, the patient's tolerance can usually be determined by injecting less than 1,000 of the bacterial vaccine and gradually increasing this amount until manifest symptoms of over-stimulation appear. If an amount slightly below the patient's tolerance is injected at frequent intervals until his condition is markedly improved, it will be found that he can then tolerate considerably larger doses of vaccine. It will be necessary to increase the dosage very cautiously in these cases and they may not even be able to tolerate a ten per cent increase each time. On the other hand many cases show marked improvement from the repeated injection of a constant minute amount. This indicates that they are unable to produce more than a very slight excess of antibodies. Factors requiring the greatest skill and experience are the determination of the most suitable interval and the optimal dose. A much larger proportion of our recent patients have obtained good results as compared with earlier ones, and we attribute much of this improvement to greater experience acquired in giving the vaccines and to the habit of submitting patients to a rigid cross-examination before deciding on each injection. This was found necessary because many patients experience difficulty in evaluating or describing their symptoms. Each one of their symptoms should be taken up separately and any new conditions should be carefully weighed. When the treatment has been given by local physicians, the percentage of good results has been considerably below that of those treated by the author personally and it is hoped that the publication of this paper will assist physicians who have obtained irregular results with this type of vaccine.

We have used subcutaneous or hypodermic injections as far as posible. Where the amount is large, it is necessary to inject a little deeper and, if local reactions follow, the injections should be equally distributed between two or more different parts of the body or deep intramuscular injections in the buttocks should be resorted to.

Optimum Dose: The determination of the optimum dose seems to offer many difficulties. In the first place, some physicians are poor mathematicians. Those of the older school have not been trained to use metric terms while many of the younger generation experience difficulty in distinguishing arithmetical progression from geometrical ratio. In the former, the absolute magnitude of the increase remains constant while the percentage increased becomes progressively smaller. In the latter, the percentage increase remains constant and it is this type that is used in vaccine therapy. Let us take an example. In the series 2, 4, 8, 16, 32, 64, the increase is constantly 100 per cent. In the series 2, 3, 4, 5, 6, 7, the increase is 100, 33, 25, 20 and 16.6 per cent respectively. One of our colleagues ordered a nurse to give "one-tenth of a cc and increase each time by one-tenth of a cc." Another associate gave his patient "one-quarter, one-half, three-quarters and one cc" of one dilution and then the same amounts of a dilution which contained eight times as many bacteria. In these instances they were using arithmetical progression. For example, in the latter case the increases were 100, 50, 33.3, 100, 100, 50, and 33.3 per cent respectively. With many patients it is dangerous to give more than a twenty-five per cent increase.

At this point the reader must be cautioned against any attempt to adhere to a fixed schedule as it will only lead to disaster. I have seen many decided failures when these vaccines, accompanied by suggested dosage lists, were sent to patients' local physicians. In spite of warnings these lists were often blindly followed.

Optimum Interval: The interval obviously depends on the patient's response to treatment. Where no untoward effects are noted in the early doses, it is often safe to allow an interval of two or three days and to prolong the interval to five, seven or ten days or longer as the treatment progresses. Most patients are able to detoxicate the smaller doses quite rapidly but with the increased amounts, a much longer time is required and the interval must be progressively lengthened. The majority of hypersensitive patients require at least a five-day interval. After they have begun to show marked improvement, this interval should be still further lengthened. Where patients are getting doses exceeding 200 millions, it is rarely wise to give the injections more often than every two weeks. In the absence of a hypersensitive state, in patients giving good response *without any symptoms of toxicity,* it is possible to increase the vaccine twenty-five per cent each time.

Danger of Overstimulation: Small amounts of vaccine stimulate antibody production but this is not sufficiently marked to confer a

1. After a course of vaccine the patient's condition was greatly improved but there were still symptoms referable to the gall bladder. Cholecystectomy was advised. At operation adhesions were found and the wall was thickened but there was no evidence of active inflammation. Culture of the tissue was negative.
2. Patient's general condition was markedly improved but the vaccine had *no effect* on his deafness.

lasting immunity. Consequently, although the patient may appear to be cured after a few doses, all his symptoms are likely to return after a very brief period. With the use of larger amounts, a more lasting immunity is conferred and, when the higher dilutions have been reached the dose repeated a number of times, there is every reason to believe that the effect is permanent. If the increase in each injection is insufficient, the patient will get only a slight benefit. In these cases the antibody stimulation is not sufficiently pronounced to produce beneficial results. On the other hand, if the vaccine is given too frequently, or the *dosage is increased too rapidly, the patient's condition may also become worse.* It is this similarity of effects of over and understimulation that causes the greatest difficulty in determining the optimum dose and interval and successful results will only come from considerable study and experience. Where the patient has been progressing satisfactorily and then presents unfavorable symptoms, it is wiser to give him the benefit of the doubt and to assume that the unfavorable results have been due to overstimulation. In this way as acute surgical condition may often be avoided. We have seen a gastric hemorrhage, an acute cholecystitis, several cases of acute appendicitis and an acute pyelitis caused by overstimulation. All of these could have been avoided if the physician administering the vaccine had stopped it temporarily after manifest symptoms of a flareup of the focal infection had appeared. Where doubt exists, we feel that it is wiser to wait a week or ten days and give an amount somewhat less than the previous dose. If lowering the dose does not produce a favorable response, the effects were probably due to understimulation and the dose should be cautiosly increased. In all these cases presenting suggestive symptoms of a focal or general reaction, we must reiterate that it is as unscientific as it is careless to increase the dose until one is convinced that the injection given will not excite a focal disturbance. Adverse reactions have given vaccine therapy a bad reputation and are usually avoidable.

An important point to remember is that many individuals possess a distinct saturation point which, however, varies from time to time. Any attempt to increase the vaccine above this point will result in severe toxic symptoms or lack of favorable response. In these instances, it is desirable to reduce the dose or to temporarily discontinue the vaccine until the patient's resistance has been built up. In some patients, poor resistance is related to low thyroid function or even to a polyglandular deficiency. Small doses of thyroid extract given to those showing lowered basal metabolic rates will sometimes improve their condition. The use of multiglandular therapy has often proved successful. In general, the lower the patient's vitality and the longer the duration of his illness, the slower will be his response to vaccine therapy.

Accuracy in measuring the dose is of paramount importance. We prefer to use tuberculin syringes. Ordinary hypodermic syringes do not permit precise measurement of small quantities and their use for vaccine therapy should be discouraged. The boiling of syringes is permissible provided the parts are allowed to become dry before being assembled. If they are put together wet, there will be an error in volume due to dilution of the vaccine with the small amount of water. Baking both the syringe and the needle is preferable. On account of the more effective destruction of spore-bearing bacteria by dry heat, insuring absolute sterility, a large number of local reactions, due to infection caused by bacteria which survive boiling, are eliminated. To facilitate sterilization, needles are placed in tubes which are constricted to prevent their points from coming in contact with the bottoms. This makes it unnecessary to stuff cotton down the bottoms of the tubes to protect the points and, therefore, eliminates the nuisance of having strands of cotton adhere to them.

Although it is dangerous to suggest dosage for the general type of patient, the following suggestions will be helpful: (1) The initial dose should be about 1,000 bacteria for hypersensitive patients and 50,000 for others. (2) If a reaction occurs, the dose should be cut to one-fourth. (3) If no reaction occurs, the dose can be increased twenty-five per cent. When the volume exceeds one cc, a proportionate amount of a stronger dilution should be used. (4) When maximum stimulation has been obtained and the patient ceases to improve, the dose should not be increased. (5) After the patient is apparently cured, he should be "weaned" from the vaccine by prolonging the interval.

A properly prepared and administered vaccine should be capable of sterilizing a focus of infection or intoxication. It would not be fair to expect a vaccine to remove kinks or adhesions that have resulted from infection or to cause the complete disappearance of calcifications, neither can it be expected to restore physiological functions that have been altered through infection. Certain types of mechanical defects will persist and these are best treated by physiotherapy or, in some cases, surgery. A patient is not considered cured until the positive complement-fiction reactions have disappeared.

In conclusion, I wish to point out that success with vaccine therapy depends on the infinite care with which minutest details are carried out. Too much must not be expected of vaccine treatment. It is to medicine what drainage is to surgery. Both may be necessary in effecting a cure.

I wish to express my gratitude to George H. Chapman for his painstaking laboratory studies of my patients, for without such investigations, this paper could not have been written.

EXAMINATION OF THE SO-CALLED "BAD" OR "NERVOUS" CHILD

By FREDERICK L PATRY, M D, ALBANY, N. Y

Neuropsychiatrist The State Education Department, The University of the State of New York

THAT the so called "bad' or "nervous" child is one of the common garden varieties of school problems which the school physician is asked to examine and treat, is not news But the fact that many of these children are neglected or given inadequate attention is a fact which should stir every school officer to put into action the best that medical science has at present to offer in helping to solve these tremendously important problems To this end the writer wishes to suggest an examination outline which has proven of sound value in the examination of such children at the Phipps Clinic of the Johns Hopkins Hospital where the author was a staff member the past two and one-half years

No one doubts the importance of a systematic approach, in medical examinations However any form of procedure has its defects as well as its merits The utilization of such helps should be largely guided by the individual case at hand as well as the trained, critical, common sense and experience of the physician

In any case of a so called "bad' or "nervous" child the following minimal, essential questions should be asked and data thereform elaborated upon according to the best judgment of the examining physician

I FACTS OBTAINED FROM HISTORY

1 STORY OF CHILD DEVELOPMENT EMBODYING,

a *Facts of inheritance* (when available) nervous breakdowns, with or without hospitalization, including rest-cures, alcoholism, epilepsy, eccentricities, geniuses or deficiencies

b *Facts of developmental data*

Birth (instrumental with injuries),

Feeding (prolonged malnutrition, with or without rickets during first 2 years of life),

Convulsions,

Age of walking, sentence formation, tidiness with urine and stools, early evidences of defective attention and ability to grasp simple requirements of biological adaptation—feeding himself, dressing, avoidance of danger, play—best when alone or with other children, etc

Habits

Regularity of sleep (bed alone, time? requirements of light, mother by bed? evidence of night terrors, sleep walking, bedwetting, etc)

Regularity of meals—fussiness over food, reactions of vomiting, gagging, etc

Habits of emotional control and disposition—shy, sensitive, timid, fearful, sulking, tantrums, explosiveness, petulance, whining, cruelty, sex curiosity

2 SCHOOL FACTS

Age on entering—kindergarten (public—private), years in each grade, mental attitudes in class room, playground report (good mixer or good leader)

Development of special aptitudes and interests

3 FACTS OF PARENTAL MANAGEMENT

a Relationship to father and mother

b Interparental relationship with particular reference to policies of child management

c Home standards with respect for civic institutions

II FACTS CONCERNING PHYSICAL STATUS

General Condition Tuberculin and other special tests, as indicated with reference to nutrition, eyesight, hearing, nose and throat status, teeth

III FACTS OBTAINED FROM MENTAL EXAMINATION

Intelligence test Personality estimate of child as revealed throughout examination and from questioning about his specific difficulties

IV FACTS OBTAINED FROM STUDY OF SOCIAL AND ECONOMIC CONDITIONS OF FAMILY

Obviously the school physician himself has not time to gather all this necessary information He should therefore utilize all the helps available—visiting teacher, social service worker, school teachers, parents, attendance officers, friends, etc, for contributive, pertinent facts Moreover, the physician should realize that he cannot intelligently treat any such case until the above information has been formulated and evaluated The cultivation of dependable systematic habits of examination will do much to give these children a better chance to balance their assets and liabilities and to shape the school resources to the needs and capacity of the individual child

For list of officers of County Medical Societies, see this issue, advertising page xxxii.

PRESERVING THE MINUTES

This issue of the Journal contains eighty-eight pages,—eight more than the usual number. The increase is caused by the minutes of the House of Delegates which will fill twenty-five pages; but the space devoted to them is well used, for they embody not only the actions taken, but also the reasons advanced by both their supporters and their opponents.

The actions of the House of Delegates are the policies of the Medical Society of the State of New York during the coming year, and are therefore of importance to every member of the State Society. It is not reasonable to expect that anybody will grasp their full meaning by a cursory reading. The minutes should be preserved by every officer of every county society.

THE AMERICAN MEDICAL ASSOCIATION

The annual meeting of the American Medical Association held in Philadelphia from Monday to Friday, June 8-12, was most successful. The seven thousand doctors who came together from all parts of the Nation were fortunate in their opportunity to take a week of one of the most comprehensive graduate courses ever opened in all phases of medicine. Making the plans for the extensive series of meetings and exhibits was a monumental piece of work, for which credit is due to Dr. Olin West, Secretary and General Manager of the American Medical Association, Dr. Paul Leech, Director of Scientific Exhibits, and Mr. Will C. Braun, Director of Technical Exhibits.

The meetings received a large amount of notice in the newspapers of every state, for the Associated Press featured every phase of the events, especially those of a spectacular nature. If the reporters erred on the side of enthusiasm and over-statement, they at least conformed to the general facts related to them by the physicians and research workers. For example, the description of the effects of an extract of the cortical substance of the adrenal glands reported by Dr. Rowntree of the Mayo Clinic, as a remedy for Addison's disease, was printed by the Philadelphia *Public Leader* under the headlines "New Cure for Fatal Malady revealed by Scientists. Doctors astounded by the description of mysterious substance routing Addison's disease. Funds for further research urged." But the disease and the remedy were described in terms of scientific clearness and modesty. Every day the newspapers carried news of the results of researches which educated the general public regarding methods of medical investigation and progress. No medical meeting ever received a greater amount of recognition or more truthful notices.

The American Medical Association meeting was housed in the new Municipal Auditorium of the City of Philadelphia, which opened its doors just in time for the sessions. The Auditorium is located on 34th Street beside the buildings of the University of Pennsylvania. Each of its two lower floors consists of a great room in which the exhibits were shown; while the scientific sessions were held in the rooms of the size of banquet halls of large hotels. Philadelphia's Auditorium was ideally suited to all phases of the meetings.

The meetings of the American Medical Association consisted of four features:

1. The House of Delegates.
2. The Scientific Sessions.
3. The Scientific Exhibits.
4. The Technical Exhibits.

The House of Delegates met in the Hotel Benjamin Franklin and discussed problems of administration, among them the old subjects of prohibition, state medicine, and the medical treatment of veterans of the late war.

New York was represented by its full quota of fifteen delegates, and Dr. John A. Card came within a few votes of being elected vice-speaker.

The scientific sessions were of special interest and were unusually well attended because pains had been taken to secure well-known speakers and to assure their being heard. The larger meeting rooms were equipped with sound amplifiers so that the speakers were heard by everybody in the halls. The acoustics of the large meeting place of the Pediatrics Section were well-nigh perfect; but there was some complaint of inability to hear well in some of the smaller halls, especially when the speakers were dull and prosy, as were a few of the impromptu discussors.

The papers read will be served in the *Journal of the American Medical Association* as medical feasts, throughout the year.

The feature of the greatest practical value was the scientific exhibits. These exhibits have always been prominent in the American Medical Association meetings, but this year the medical schools, laboratories, and research hospitals sent their best men and lecturers to explain the exhibits to any doctor who cared to stop at their booths. Moreover, the managers of the exhibits enforced the rule that every booth should have a demonstrator constantly present. Some of the most noted clinicians and research workers in the land were ready to talk informally, face to face, with any doctor who chose to stop at their booths. The effect of this intimacy will doubtless be that the great number of doctors who thronged the exhibits hall carried away friendly impressions of the medical leaders of all parts of the land.

Over two hundred exhibits were shown covering every phase of medicine, even to an abscess of the tooth of a saber-toothed tiger that lived one hundred thousand years ago.

The technical exhibits were of equal interest and value with those of the scientific departments. Here the manufacturers of everything needed in medicine showed their wares and explained their use. To see the newer instruments and apparatus and hear their use explained in the treatment of disease was of as much practical importance and value as to learn about the disease from the scientific exhibitors.

The managers of coming sessions of the

American Medical Association will doubtless repeat the up-to-date features of this year's meeting; and if they do, the glowing reports of the seven thousand medical visitors of this year will inspire an attendance of double that number next year.

THE HOUSE OF DELEGATES

This Journal contains the minutes of the House of Delegates beginning on page 820 and filling twenty-five pages. Every effort has been put forth to make these minutes complete and accurate; but back of the act of recording them was the clearness and dispatch with which the business of the House was conducted by the Speaker, Dr. John A. Card, and the Secretary, Dr. D. S. Dougherty; and this in turn depended largely on the good judgment of the reference committees. The preparation of the minutes may be said to have been begun when Dr. Card, the Speaker, announced the personnel of the reference committees in the Journal of May first. The success of printing the annual reports and the names of the members of the reference committees a month before the meeting is an effective answer to the hesitation of most State societies to publish their annual reports and the committees in advance of the meeting.

The minutes of a deliberate body, such as the House of Delegates, may be written from either one of two points of view:

1. They may be literal transcripts of every remark and technical action.
2. They may be descriptive, and record only summaries of what was said and done.

The minutes this year combine the two features. Many debates are published nearly in full in order to record the sentiments and views held by the members. On the other hand, the account of the election of officers is limited to the names of those elected.

The editors have followed the precedent adopted in 1927 of printing the minutes with four distinct features:

1. Separating the minutes into paragraphs, each with a descriptive title.
2. Numbering the paragraphs consecutively.
3. Making cross references to the paragraphs bearing on each action.
4. Preparing a complete index of the paragraphs.

These four features will be most fully appreciated only by those who have frequent occasion to consult the minutes. In the absence of these features, noted in most minutes recorded in State Journals, one has great difficulty in reading the minutes intelligently.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Personal Publicity: The following editorial on personal publicity which appeared in this Journal of July, 1906, could well have been written today:—

"A physician in Louisiana has brought suit against a newspaper which published the report of a case which in newspaper parlance was 'unique.' It set forth that many physicians had treated this patient's hip trouble without success until the plaintiff, who was a close student of the methods of Professor Lorenz, took hold and affected a cure. The story was a straightforward statement which had been given to the reporter by the grateful father of the patient, and was given with a feeling of gratitute and kindness towards the physician who had cured his child.

"The doctor brought action against the paper, and was decided against by the lower court. The Supreme Court, however, reversed the decision, and ruled that, while the simple matter of sentiment could not be considered, yet it was possible that the plaintiff had actually sustained damages by this publication. It is not necessary that a damaging statement shall be made in terms of defamation and slander. Words of apparent praise may often have a damaging effect. The physician in this case, the court held, had objected to having his name paraded before the public in the same manner as is practiced by quacks; and knowing that he desired that his professional work should not be advertised in this manner, the paper in question printed an adulatory statement concerning his treatment of a certain case in which the real facts were overdrawn, and in which the impression was presented to his professional colleagues that he had represented to the family that the case was 'unique' and that his cure was extraordinary, when as a matter of fact neither of these was true. He was justified in claiming damages for having the paper represent him as pursuing the policy of the quack."

MEDICAL PROGRESS

Essential Hypertension.—Marcus Backer thinks it is justifiable to state that the enthusiastic rush for the best treatment of essential hypertension has occupied a too large part of the bulky literature on this subject, that the keynote in the prevention and therapy has not yet been struck, and that little light has been thrown on the etiology of the condition. While a variety of contradictory opinions have been expressed concerning the etiology, there is no difference of opinion that increased resistance of the peripheral vessels is the essential factor in the etiology of hypertension. A review of some of the theories advanced to explain the inability of the arterioles to relax leads to the conclusion that the autonomous innervation of the arterial system responds to a multiplicity of stimuli, that the nervous tracts which effect a change of the peripheral arterial resistance are manifold, and that the combination of these circumstances allows for a wide variety of physiological and pathological possibilities. These pathological possibilities depend upon the specific make-up of the autonomous nervous system, which the author believes is the dominant factor in patients suffering from hypertension. He has observed that certain individuals, who have worked most strenuously for two or more decades, and whose lives are full of worry and excitement, have at all times either a normal or a subnormal blood pressure. Similarly, the well-known occurrence of numerous instances of hypertensive disease in the same families leads to the belief that vascular resistance primarily depends upon the fundamental fabric of the particular autonomous nervous system as such. In the light of these considerations, essential hypertension is reduced to the rank of a mere symptom, and is to be viewed solely as a manifestation of a certain abnormal type of constitution. Whether this abnormality concerns the constitution of the vegetative nervous system alone, or whether it may possibly be correlated independently with other constitutional abnormalities (endocrine glands and other hormone-producing tissues), is not known. Backer offers the idea of a constitutionally increased neuro-muscular tonus of the arterial system simply as a starting point which suggests a number of questions for investigation.—*American Journal of the Medical Sciences*, May, 1931, clxxxi, 5.

Incomplete Forms of Gout Attacks.—It seems not yet to be generally known, according to L. Schmidt and E. Wohlstein, that in occasional cases where there is defective metabolism, for example in the uratic diathesis, skin changes may appear in a vicarious sense during an attack of gout. This is illustrated by the case of a man of 71 who had suffered with occasional attacks of gout for many years, and in whom repeated uric acid determinations in blood and urine had established beyond question a diagnosis of uratic diathesis. From his own account this patient had been subject at a later period to feverish attacks during which, in addition to changes characteristic of the uric acid picture, there were redness and swelling of the skin without the least symptoms in the joints. This alteration of the cutaneous tissue can only be explained as a vicarious manifestation in which for some reason or other the otherwise painful joint symptoms were lacking. In other words the attack of gout played its part externally, so to speak, in the skin. A closer pathogenetic study of the disease process finds further points of support for this opinion. The essential nature of gout consists in a faulty uric acid excretion, which is originally due to an increased affinity, chiefly of the mesenchymal tissue, for uric acid. The effort at retention must be a histogenous characteristic of the uratic organism. The so-called acute attack of gout gives the impression of being a natural defensive action on the part of the organism oversaturated with uric acid. As a result of the attack the uric acid content of the blood falls and the amount excreted in the urine rises. The liberation of the flood of uric acid evidently relieves the vegetative nervous system which has been irritated by the greatly changed blood chemistry, and one may regard this state of irritation of the autonomic nervous system as a catalytic of the gout attack. Just as states of irritation of the vegetative nervous system frequently cause skin eruptions, such as urticaria, herpes, erythema exudativum multiforme et nodosum, etc., so may they likewise in exceptional cases of gout produce skin alterations.—*Münchener medizinische Wochenschrift*, April 3, 1931.

The Etiology of Acrodynia.—To the symptoms of acrodynia, which Bilderback described under the six P's—pain, pink hands and feet, peeling, prostration, paresthesia, and perspiration—William Weston, Jr., adds a seventh,

photophobia, which he finds to be universal in this disease. With regard to the etiology there are two views: (1) It is caused by nutritional deficiency; (2) it is due to focal infection. Rodda thinks tonsillectomy is a specific cure for the disease. In the author's opinion it should be far from internists and pediatricians to advise tonsillectomy during the active stages of acrodynia, especially if it has become an infection. He believes the disease is due to nutritional deficiency, since practically all patients give a history of undernutrition and gradual loss of weight, since the onset is slow, and since most of the cases are sporadic. Breast-fed infants, whose mothers are apparently in excellent nutritional condition, develop acrodynia, but upon the addition of vitamins A and B to their diets in sufficient quantity, the disease clears up rapidly. Weston reports three cases in which the patients showed various degrees of involvement. All recovered without tonsillectomy; in only one were the tonsils diseased. All were given a well balanced diet rich in vitamins. The results in these cases strongly indicate a lack of proper diet as the cause of the condition. A laboratory study of the throat and nasal secretion in these cases showed the usual bacterial flora, with a preponderance of *Staphylococcus aureus* and non-hemolytic streptococci in the order named. Because of the lowered vitality and resistance of the patient, infection is invited, especially in the mucosa of the nasopharynx.—*Southern Medical Journal,* May, 1931, xxiv, 5.

Does Nicotine Cause Abstinence Symptoms?—Up to the present time, says Hermann Beers in the *Münchener medizinische Wochenschrift* of March 27, 1931, true abstinence symptoms such as follow the withdrawal of opium, morphine, cocaine, and to some degree, alcohol, have not been observed when nicotine is withdrawn either gradually or abruptly. The most that has been recorded in such cases has been slight motor restlessness, psychic irritability, and incapacity for concentration. A case is now reported in which a woman of 42 had a typical attack of bronchitis lasting about 14 days, after which the fever, cough, and pain in the chest disappeared, leaving no objective signs of morbid changes on repeated examination. However, the patient failed to convalesce, and exhibited prostration, muscular weakness, trembling in hands and feet when she tried to get up from bed, mimic restlessness, a sullen expression, weak tremulous voice, and cold feet. Examination of blood, urine, and feces was negative. The patient had the delusion that she was going to die, and begged for poison. The discrepancy between the objective findings and the profound depression led Beers to make inquiry as to her possible addiction to some habit-forming drug. On learning that she had been accustomed before her illness to smoke 30-40 cigarettes a day with deep inhalation, he recommended that she resume the practice. A single day brought definite improvement to mind and body, and by the third day she was back in her normal condition, stating that she had never felt better. Although a single case proves nothing, there is every reason to believe that this was an instance of abstinence symptoms following withdrawal of nicotine. It is conceivable that the widespread smoking of women, a new phenomenon, is bringing to light a greater sensitivity and a lesser inhibiting power in them than exists in men, as seems to be the case with alcohol. The subject deserves further study.

Post-Operative Vomiting.—Bessie E. Cook, writing in *The Lancet,* April 18, 1931, ccxx, 5616, presents a comparative study of 500 patients who had ether and an equal number who were given gas and oxygen. Of the first group 43¼ per cent, and of the second group 56 per cent, were not sick at all. In every case there was a slight advantage on the side of gas and oxygen. In seeking the reason for this difference, it was found that it was partly a question of the depth of the anesthesia, but since surgeons who ask for deep anesthesia are usually those whose technique would produce reflex signs in patients not quite so deeply anesthetized, probably both causes, surgical trauma and excessive anesthesia, may act at the same time. There were 20 deaths in the gas group and 30 in the ether division. The patients receiving gas left the hospital on the average a day or more sooner, and their progress was really more rapid, than those taking ether. Both the staff and patients who had previously taken ether confirm the great difference in the immediate well-being after operation when gas is used. With ether there is often a heavy stuporous nausea lasting for several days, and the taste of the drug lingers, since its complete elimination may take a week. Gas and oxygen are eliminated within a few seconds after the close of administration. Possibly some of the sickness occurring after gas may be attributed to the fact that patients are sooner able to move voluntarily in bed. Vomiting in these groups of patients was only one-third to one-half as frequent in men as in women. This is probably due to the fact that the nervous and endocrine systems in women are easily affected by both physical and psychical trauma. The stomachs of men are frequently in better training to be insusceptible

to foreign substances such as would produce nausea in digestive tracts less case hardened. Men, however, are more liable to coughs. This may be explained by the fact that they usually require a great deal more of the anesthetic than women. The figures show that with gas and oxygen there is 50 per cent less likelihood of chest complications than with ether, if given intensively. The point to be emphasized is that since trauma is of such great importance in even the minor discomforts after operation the aim should be a gentler and still gentler technique in surgery. The use of gas means that the patient's respiratory and circulatory systems do not suffer so great an upset, and with less trauma at the hands of the gas-accustomed surgeon, they recover sooner from the minimum of handling.

Treatment of Hyperemesis Gravidarum with Glucose and Insulin.—Bruno Kriss, writing in the *Münchener medizinische Wochenschrift* of March 27, 1931, says that the advantages of this method are still unknown to the majority of physicians outside the ranks of specialists. He publishes an instructive case in a woman of 32 who in the second month of her first pregnancy suffered with hyperemesis with severe toxic symptoms indicating liver injury. This was shown by the presence in the urine not only of large amounts of acetone and bilirubin but also, and more especially, of leucin crystals. The appearance of leucin in the urine is regarded by students of metabolism as extremely unfavorable in prognosis, pointing to a high-grade liver destruction. This consideration induced Kriss, who was already administering insulin and glucose, to interrupt the pregnancy. Vomiting continued, however, almost without cessation. The patient suffered with transient losses of consciousness, restlessness, and dyspnea, while large masses of leucin crystals continued to appear in the urine, with abundance of ketone bodies, albumin, and urobilinogen 1:528 positive. She was now given twice daily 150 c.c. of a 40 per cent glucose solution by rectum and 15 units of insulin subcutaneously, that is, 120 gm. glucose and 30 units of insulin per day. These large amounts were well tolerated. By the fifth day the general condition was already definitely improved; on the tenth day the bilirubin disappeared from the urine, and on the twelfth the leucin and acetone, vomiting ceasing on the eleventh day. The case shows the paramount necessity of protecting the liver from loss of glycogen. A method that can accomplish this points the way to the successful treatment of dangerous liver conditions. The starting point of pregnancy toxins is chiefly in the liver. The histologic picture of both the animal and the human liver in pregnancy shows depletion of glycogen and infiltration of fat. Glycogen serves as a protection for the liver cells. Its loss or even diminution invites injury and finally destruction of these cells, followed by fat infiltration. The organism cannot altogether protect itself; products of fat disintegration (acetone bodies) remain in the blood, from which they are only in part excreted in the urine. The case here outlined teaches that a toxic liver of very severe degree, with destruction of hepatic tissue persisting despite a therapeutic abortion, could be brought to a halt and further destruction of liver cells prevented by treatment with glucose-insulin to restore normal metabolism.

Anaphylaxis to Insulin.—It is a mistake, say A. Cade, Ph. Barral, and J. Roux, to attribute, as most authors do, anaphylactic phenomena after use of insulin to impurities in the insulin. These workers, having observed various types of reactions, local and general, carried out studies to learn the exact pathogenesis of such reactions, and to determine whether they were due to impurities in the insulin or to anaphylaxis. Three groups of guinea pigs were injected intraperitoneally, the first with 0.1 c.c. ox serum, the second with 0.1 c.c. glycerinated emulsion of ox pancreas, and the third with 4 units of purified insulin. After an interval of 30-40 days, some of the animals in each group were injected intradurally with 0.01 c.c. ox serum, some with 0.1 c.c. glycerinated emulsion of ox pancreas, and some with 2 units of insulin. All of the animals in the first two classes and one-half of those in the third presented phenomena of shock from a second injection of the same substance they had received before. But those sensitized to ox serum or ox pancreas did not suffer a shock after a second injection of purified insulin, nor did the guinea pigs which had been sensitized to purified insulin suffer shock upon a second injection of serum or emulsion of beef pancreas. Finally an attempt was made to sensitize guinea pigs by means of another commercial insulin of a type that had been systematically "incompletely purified." Five of the 6 animals so treated showed intense shock, and one of them died. From these experiments it is seen that insulin appears to behave like a specific antigen and to create sensibility in the same degree as the other antigens that have been most generally incriminated, notably foreign proteins. It is concluded that pure insulin is capable of producing anaphylactic phenomena and that it constitutes in itself a specific antigen. Insulin incompletely purified causes these in a more intense degree, because of the intervention of

foreign proteins. Clinically, however, these accidents are rare, at least with pure insulin. They teach the necessity first of using the pure article, secondly, of prescribing a desensitizing treatment, and sometimes the temporary interruption of treatment.—*Bulletin de l'Académie de Médecine*, March 31, 1931.

Reflexotherapy of Headaches.—By this term is meant, says Georges Schoengrun, the control of headache by applying suitable treatment to the trigeminal-sympathetic fibers in the nasal mucosa. It is commonly known that if the tip of the middle turbinated bone is touched with a probe a series of reactions follows instantaneously; lacrymation, reddening of conjunctivae, and a copious secretion of nasal mucus. More energetic stimulation of this region causes perspiration, dilatation of pupils, flushing of the face and even of the neck and chest, and may, if prolonged, produce tachycardia and even syncope. In short, the irritation excites nerve fibers coming from an exceptionally rich network in which the sympathetic, parasympathetic, and trigeminus all participate. The disturbances caused by exciting the sphenopalatine ganglion are vasomotor and secretory. In the light of recent theories clinically confirmed we are forced to conclude that the sympathetic is an anatomical entity that cannot be dissociated, traversed by a nervous influx from end to end. When excited, the ganglia scattered over its network seem to constitute relays which not only reinforce the initial excitation but transform it with reference to an adaptation to this or that organ. It can thus be seen that by a simple touch at a point where certain nerve fibers emerge from the sympathetic nerve we provoke reflexes that may extend for a long distance from their origin. These considerations have a bearing on the origin of certain headaches in subjects of abnormal sensitivity, of which clinical observation cannot precisely reveal the cause. Schoengrun undertook to control these headaches by introducing into the nasal cavity a substance that should be at once caustic and anesthetic. He applied to the retroturbinal region of the nasal mucosa a mixture consisting of equal parts of carbolic acid, menthol, and cocaine in order to produce simultaneously an inhibition and a regulation of the nerve centers, that would permit the organism to acquire a new aptitude for regaining its normal coefficient of stability. He has used this treatment in 55 cases, resulting in 38 cures, 4 improvements, 12 failures and 1 aggravation. Among the cures were 9 cases of periodic migraine, 7 of supraorbital and frontal neuralgia, sequels of old sinusitis, 2 of zona ophthalmica, 4 of occipital headache, and 5 of neuralgia temporally or frontally localized. In a general way it may be said that reflexotherapy seems to act in a quasi-specific manner on the element of pain in the majority of headaches associated with other functional troubles.—*Bulletin de l'Académie de Médecine*, April 21, 1931.

Ultraviolet Radiation—What, Why, and How.—George F. Crosley states that ultraviolet radiation is that having a wave length between 1700 and 4000 Angström units. Only wave lengths between 2500 and 3100 Angström units. produce effects in which the physician is interested. There are three principal effects of ultraviolet radiation in this region—direct germicidal, benign inflammatory reaction, and vitamin D production through the action on ergosterol. In general, the shortest radiations have the greatest germ killing power, which decreases in intensity with increase in wave length. Radiations between 2700 and 3100 Angström units create a noninfective benign inflammatory reaction in the tissues with all the advantages of increased blood supply, phagocytosis, and temperature without the production of the bacterial toxins incident to ordinary inflammatory reactions. The third and the most important action of ultraviolet radiation is the conversion of ergosterol found in the skin into vitamin D. As there is marked variation in the amount of therapeutic ultraviolet radiation in sunlight, the amount being small during the winter months, so is there variation in the amount of vitamin D in butter, eggs, and milk. Retention of calcium is dependent upon a sufficient amount of calcium and phosphorus in the diet, as well as of sufficient vitamin D to act as a catalyst and permit the utilization of calcium and phosphorus. Deficiency of calcium and phosphorus causes rickets, spasmophilia, osteomalacia, and tetany and predisposes to hemorrhage, to catarrhal conditions, increased anaphylactic reactions, increased muscular and nervous instability, digestive disturbances, and susceptibility to disease. Available evidence indicates that the natural avenue of absorption of vitamin D is through the skin from activated ergosterol rather through the digestive tract. Observations have shown that in two localities in which the diet is the same and rich in vitamin D there is a difference in the incidence of rickets corresponding to the difference in the amount of ultraviolet light in the sunlight. The sun is not the ideal, and during the winter months is impractical as a source of visible, infrared, or ultraviolet radiation for therapeutic use. Hence dependence must be placed upon artifical sources. Radiations from a carbon arc do not closely approximate those from the sun. The ideal source is that which will give the greatest volume in the region desired, taking into consideration the matters of safety, convenience, sanitation, economy and scientific accuracy of control of output. The best quartz mercury arc lamps make possible the accurate control of lamp voltage and therefore of ultraviolet output, and hence make possible accurate dosage. — *Physical Therapeutics*, May, 1931, xlix, 5.

LEGAL

COURT'S POWER TO VOID JURY'S VERDICT ON GROUND OF BIAS

By LORENZ BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

An extremely interesting and important decision was recently handed down by one of the Appellate Courts of this State. The decision in question dealt with the right of the Court to set aside the verdict of the jury upon the ground that the said verdict did not truly represent the unanimous view of the jurors. The case arose on the following state of facts:

The plaintiff, a concert pianist, was homeward bound on one of the defendant's steamships. She claimed that she sustained injuries by being precipitated down a flight of stairs by reason of the alleged negligence of the defendant steamship company. The action was on trial for three days before a judge and jury, and after the trial court had charged the jury he ordered them to return a sealed verdict on the following morning.

At this point, it is important to explain the meaning of the term, "sealed verdict." It frequently happens that a case is submitted to the jury late in the afternoon. Under such circumstances the trial court very often directs that the jury return a sealed verdict to be opened the following morning. Instructions are left by the trial court with the officer in attendance upon the jury during their deliberations, as to the length of time that they are to be locked up, and if they do not agree upon a verdict before that time it must be so recorded in writing. If they do agree upon a verdict, each of the jurors must individually sign their verdict on the form which is then placed in a sealed envelope and given to the clerk who keeps it in his custody until the following morning when it is opened by the trial court in the presence of the jury who are instructed by the trial court to return so that they may be present when the verdict is opened.

In this case it appeared that the jurors signed and gave to the clerk a paper stating that they had found a verdict in favor of the defendant. The next morning, however, before the court convened and before the sealed verdict had been opened, five of the twelve jurors having overnight reconsidered their views as expressed in the sealed verdict, appointed one of their number to inform the justice presiding at the trial that they wished to recall their finding in favor of the defendant. By reason of the fact, however, that the trial court was busily engaged on the morning in question, this juror did not approach the trial court nor was the trial justice advised that some of the jurors wished to reconsider their previous decision. In accordance with the usual practice therefore, the sealed verdict was opened and read into the record and there was no statement made by any juror in open court at that time that he dissented from the views expressed in the sealed verdict. The plaintiff's attorney made the usual motion to set aside the verdict on the grounds that it was against the weight of the evidence, contrary to the evidence and contrary to law, which motion was duly denied by the trial justice.

On the afternoon of the same day, one of the jurors went to the office of plaintiff's attorney and told him that the verdict did not represent his views nor the views of four other members of the jury. The plaintiff's attorney immediately took this juror to the justice who had presided at the trial, but the court felt that it would be improper to speak to the lawyer or the juror in the absence of the opposing counsel. Thereupon this juror as well as four others made an affidavit in which they said in part:

> "We feel strongly that a serious wrong has been done to the plaintiff in this action in the verdict as it now stands. The said verdict at the time of its acceptance by the court did not represent our convictions in the case. * * * We are prompted in our desire to have the verdict set aside by the fact that at no time, either before or after its being read in open court, did said verdict represent our true and honest judgment of the merits of this case. We feel that said verdict is a miscarriage of justice; that a serious wrong has been done to the plaintiff, and that it is our duty to join in this application to have the said verdict set aside."

On the basis of this affidavit the plaintiff's attorney duly moved to set aside the verdict, urging three specific grounds: First, that one of the jurors, when examined as to his qualification prior to being sworn, failed to disclose the fact that he had been an investigator and adjuster of claims for upwards of twenty years; second, that this juror during the deliberation of the jury through threats rendered impossible a careful consideration of the evidence and resulted in a verdict for the defendant contrary to the honest convictions of a number of the jurors; and third, that prior to the opening of the sealed verdict and its acceptance by the court, one of the jurors in behalf of himself and several others had unsuccessfully sought to call to the attention of the court that the said verdict did not express their conscientious

views and that they desired to change the said verdict.

In regard to the conduct of one of the jurors in insisting at the outset that a verdict must be returned in favor of the defendant, the affidavit of one of the jurors in support of the plaintiff's motion to set aside the verdict contained the following statement:

"Immediately upon the taking of the said vote, said juror number 12 stated to the other jurors: 'We may as well understand right here and now that there has got to be a verdict for the defendant here.' Some of the jurors, including myself, remonstrated with him and attempted to point out to him wherein the evidence in this case showed that the defendant had been negligent in failing to have guarded against the accident which resulted in the serious injuries to the plaintiff, but said juror X stated: 'Nothing that you can say can help. We have got to find a verdict for the defendant. I have been an investigator and adjuster for shipping companies for over twenty years, and I know all about these cases. You may as well make up your minds to find a verdict for the defendant. If necessary we will sit here for three days and three nights until you do so.' The other members of the jury tried to discuss the evidence and reach a verdict in accordance therewith. Calm and deliberate discussion was rendered impossible by the belligerent talk and attitude of said juror X. He continued to insist that there was no use discussing the case because it would do no good, and that we would have to bring in a verdict for the defendant. I then told the foreman that under the circumstances no purpose would be served by continuing the session, and asked that he send word to Judge A as to the situation. This the foreman refused to do. We remained in the jury room altogether about two hours. During that time several votes were taken, and the jurors who had voted for the plaintiff, gradually yielded to the domineering and bulldozing methods of said juror X."

The trial court before whom the plaintiff's motion came, after due consideration of all the facts, set aside the verdict with the following opinion:

"The juror who sought the attention of the court before the verdict was recorded or even opened, was acting for himself and other jurors in order that it might be brought out that the sealed verdict did not express their views. I am satisfied that in the haste and confusion of the calendar I unwittingly proceeded in a way which resulted in there being recorded a verdict which at that time did not by far represent the unanimous conclusion of the twelve triers of fact. Otherwise either counsel or the court would have caused them to be polled and would have immediately discovered the true situation. Accordingly, in view of what happened at the time, and on reading the papers which have been filed, the court on its own motion and to correct a wrong for which, perhaps, the court was unintentionally responsible, will set aside the verdict."

The defendant promptly appealed to the Appellate Division where the action of the court below in setting aside the verdict was sustained by a divided court, three of the justices voting that the verdict should be set aside and two holding that it should not. The majority opinion said in part:

"It seems to me, under the circumstances of this case, that the action of the justice presiding at the trial in vacating the verdict was justified. In this case the court directed a sealed verdict, but until said verdict was actually recorded and the jurors discharged any of the jurors had the right to withdraw his consent to a verdict. A so-called sealed verdict is no more than the agreement reached by the jurors. It does not become final until it is read into the record and the jurors discharged. I know of no distinction between a sealed verdict and an oral verdict. Prior to the discharge of the jury it was the prerogative of any juror to change his mind and to challenge the verdict about to be rendered. * * *

"In our opinion there can be no question as to the right of any juror serving at the trial, notwithstanding the fact that such juror had agreed to the form of the sealed verdict prior to said verdict being actually recorded, to change his mind and to announce the same to the court. The verdict in this case, as recorded, was not the unanimous verdict of the jury. It did not correspond to the intention of the twelve jurors at the time the verdict was rendered."

There were vigorous dissenting opinions by two justices of the Appellate Court. These opinions pointed out that five jurors had signed affidavits on behalf of the defendant contradicting the allegations in the affidavits of the jurors who sought to have the verdict set aside. In one of the dissenting opinions it was said:

"This proceeding appears to be an attempt by an unsuccessful party to set aside a verdict by securing affidavits from jurors to impeach their verdict. In this case there was a sealed verdict, signed by each juror, including the jurors who are now attempting to repudiate their action in voting for a verdict for defendant. Juror No. 12 was the last one to sign the sealed verdict after the jurors who now say they were coerced by him had voluntarily signed the verdict.

"The attorney for plaintiff appears to place the responsibility for the verdict upon the trial justice or his own failure to challenge a juror who was engaged in a business that might affect his judgment. He sets forth in his affidavit: 'Ordinarily I should have excused said juror X as a juror merely because of the fact that he was engaged in a shipping business, as had been stated by him. Because of the urgings of the court, however, that the selection of jurors be completed expeditiously, I relied upon said juror X's assurances of impartiality and permitted him to remain on the jury.'

"There appears to be no merit in the statement that the juror X concealed anything. It appears that he stated he was engaged in the shipping business, and the attorney for plaintiff frankly states that he was impressed by that fact and that he would not ordinarily accept a man engaged in that business as a juror in a case of this character. This clearly emphasizes the fact that there was nothing concealed; that the attorney knew the nature of the juror's business and had an opportunity to challenge him if he believed the juror, because of such business, would be influenced in favor of the defendant.

"It is difficult to understand how the influence of juror X became so over-powering as to be responsible for the verdict in favor of the defendant. This confession of weakness on the part of several jurors is highly improbable and is contradicted by several other jurors, who have submitted affiidavits to the effect that the verdict for defendant was reached after due deliberation and a free and full discussion of the facts by all the members of the jury, without the influence of juror X or any other juror.

"B, a juror, says: 'There was a fair and honest discussion of all the facts in this case. We had argument and discussion and went into the case thoroughly. I deny here that there was any bulldozing or any other

method of coercion used in reaching this verdict, nor any violence threatened on the part of anybody. Some were for the plaintiff and finally voted for the defendant, and reached their verdict freely and willingly. There was nothing unusual in reaching the verdict in this case. I signed my name to the stated verdict as did all the other jurors. This verdict was reached in fairness, and finally all the jurors reached their verdict on the facts. Nobody dominated the other, and each had his own say. I signed the paper for the defendant, and state every other juror did so willingly.'

"To the same effect are the affidavits of jurors C, D, E and X.

"E, one of the jurors, says: 'At all times each juror discussed the case pro and con. At no time during my discussion of the case was I influenced and voted strictly on the evidence as I heard it produced in court and after I applied the law as the judge gave it to me.'

"Five jurors have made affidavits denying the allegations of jurors F, G, H, I and J.

"We therefore have the affidavits of five jurors that the verdict was brought about by coercion. Opposed to such allegations we have the affidavits of five other jurors, D, C, B, E and X, that there was nothing unusual in the discussion of the evidence or the finding of the verdict.

"If verdicts are to be set aside on conflicting affidavits of jurors after they have been rendered in a case of this character we should soon have a chaotic condition. It has so frequently been held that a verdict cannot be impeached by the affidavit of a juror that the law seems to be well settled on that subject. This was a sealed verdict, to which were affixed the signatures of all the jurors before the verdict was finally submitted to the court."

In the other dissenting opinion, one of the justices expressed his disapproval of the action of the trial court in setting aside the verdict in the following language:

"No verdict in a closely litigated case would be immune from attack if the courts are to give heed to the expressions of jurors after the verdict has been rendered. Lawyers of experience know that jurors, when interviewed after the rendition of a verdict, frequently say that they would have found the other way if they were to reconsider the matter or that they had been misled by the emphasis placed on certain evidence or had not fully comprehended the court's charge. Rarely can a juror resist the importunities of the defeated and disappointed litigant and refrain from giving that consoling balm. A field would be opened to those who might seek by unfair or corrupt means to turn a juror from his recorded decision and utilize his change of view to nullify the verdict. Courts would be largely employed in sifting these affidavits, and jury trials would result, not in decision determinative of the issues in dispute, but in creating new realms of controversy.

"There is wisdom in strictly enforcing the ancient rule which forbids the impeachment of a verdict by the affidavit of a juror. The language of one authority is pertinent: 'The danger would be infinite if an affidavit could be received from a juryman for the purpose of setting aside a verdict.'

"It is well settled that affidavits of jurors are inadmissible for the purpose of impeaching their verdict (citing cases).

"If the affidavits of the jurors be excised from the record and discarded there is nothing upon which the order of the trial court can be based. All that remains is some proof that one juror endeavored to confer with the court in the morning before the sealed verdict was opened, but was unable to speak to the court before entering the jury box with his fellow jurors.

"It is an unvarying practice that the clerk, after calling the roll, asks whether the jury have reached a verdict, and upon an affirmative response, the sealed verdict is opened and read. When this was being done and the jury harkened to its record, none of the jurors gave utterance to anything to indicate that the verdict which they had signed during the prior evening, and the recording of which they were then witnessing, was not their real verdict. Had plaintiff's counsel so requested the jury might then have been polled, but he waived his rights in that respect by failing so to move. These formalities are strictly followed because they are designed for the prevention and correction of error. They must be carried out while the jury are still serving as an arm of the court. After the verdict has been so received and recorded, and the jury have been discharged, and the court, as here, has declined to disturb it upon a motion made upon the court's minutes, that verdict, so hedged about in its reception and entry, must be regarded as having settled the issue submitted to the jury for decision. No juror can then, after having been discharged from consideration of the case, be heard to impeach his verdict and cause the litigation to be reopened.

"Were the rule otherwise the effective and final disposition of controversies would be thwarted and the present vast amount of litigation occupying the time of the courts would be greatly increased. The rights of parties throughout a controversy are carefully safeguarded under our procedure. No litigant should be unduly vexed with repeated trials of the same dispute. The verdict of a jury reached upon conflicting evidence under the guidance of a full and fair charge imports finality and is not to be lightly tossed aside upon the claim of some of the jurors that they have experienced a change of view. Care must be taken that the doors be not thus opened to a flood of unending litigation."

It is quite probable that the case will receive the consideration of the Court of Appeals, the highest court of this State. The writer agrees with the dissenting opinions in this case. If the majority opinion should receive the sanction of the Court of Appeals, it seems obvious that disgruntled and unsuccessful litigants will seek, upon one pretext or another, to obtain the affidavit of one or more jurors with a view to setting aside the verdict rendered. The result of this practice has been so fully and ably treated in the dissenting opinions discussed in this editorial, that it is unnecessary to add anything to what has already been said. It is sufficient to point out that the majority opinion opens the door to a flood of unending litigation.

HOUSE OF DELEGATES

MINUTES OF ANNUAL MEETING

The 125th Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Hotel Syracuse, Syracuse, New York, on Monday, June 1, 1931, at 2 P. M., Dr. John A. Card, Speaker; Dr. Daniel S. Dougherty Secretary.

1. Committee on Credentials

The Speaker: The first order of business is the report of the Reference Committee on Credentials; Mr. Secretary.

The Secretary: Mr. Speaker and gentlemen, there are no disputed delegations. All gentlemen present have a right to vote. See Sections 8 and 49.)

The Speaker announced that the Secretary would call the roll by Counties for the purpose of determining the presence of recognized delegates.

The Secretary thereupon called the roll by Counties.

The Speaker: There being a quorum present, we will proceed to the business of the house.

2. Approval of Minutes

The Speaker: The first order of business will be the reading of the minutes of the previous meeting.

The Secretary: I move that the readings be dispensed with, and that the minutes be adopted as published in the New York State Journal of Medicine, July 1, 1930.

Motion seconded and carried.

3. Reference Committees

The Speaker: I shall now ask the Secretary if he will read the list of Reference Committees.

The Secretary read the following reference committees.

Reference Committee on the Report of the President: Luther F. Warren, Chairman, Kings; Floyd S. Winslow, Monroe; Augustus J. Hambrook, Rensselaer; Joseph B. Hulett, Orange; J. D. Olin, Jefferson.

Reference Committee on the Reports of the Secretary, The Council, Councillors and The Board of Censors: William A. Krieger, Chairman, Dutchess-Putnam; Terry M. Townsend, New York; Frederick H. Flaherty, Onondaga; Horace M. Hicks, Montgomery, Charles H. Goodrich, Kings.

Reference Committee on the Reports of the Treasurer and Trustees: Aaron Sobel, Chairman, Dutchess-Putnam; Charles C. Trembley, Franklin; Andrew Sloan, Oneida; David W. Beard, Schoharie; Luther A. Payne Sullivan.

Reference Committee on the Report of the Committee on Legislation: Walter Ludlum, Chairman, Kings; Frederic C. Conway, Albany; B. Wallace Hamilton, New York; Albert A. Gartner, Erie; Leon M. Kysor, Steuben.

Reference Committee on the Report of the Committee on Scientific Work and The Committee on Arrangements: Irving Smiley, Chairman, Bronx; Milton P. Messinger, Genesee; Louis A. Van Kleeck, Nassau; Frederick J. Schnell, Niagara; Milton G. Potter, Erie.

Reference Committee on the Reports of the Committee on Public Health and Medical Education and Committee on Cancer Prevention: Reeve B. Howland, Chairman, Chemung; George M. Fisher, Oneida; Thomas M. Brennan, Kings; Carl Bettiger, Queens; Clyde C. Lytle, Ontario.

Reference Committee on the Report of the Committee on Medical Economics: De Witt Stetten, Chairman, New York; Cornelius J. Egan, New York; Charles R. Barber, Monroe; Charles E. Padelford, Orleans; Edgar Bieber, Chautauqua.

Reference Committee on the Report of the Committee on Public Relations: George W. Cottis, Chairman, Chautauqua; Harrison Betts, Westchester; William R. Thomson, Wyoming; Walter A. Calihan, Monroe; John D. Bonnar, Erie.

Reference Committee on the Report of the Legal Counsel: C. Knight Deyo, Chairman, Dutchess-Putnam; Luzerne Coville, Tompkins; Samuel M. Kaufman, New York; William P. Howard, Albany; Frank M. Dyer, Broome.

Reference Committee on the Reports of the Committee on Medical Research and the Committee on Periodic Health Examination: Edward R. Cunniffe, Chairman, New York; Willard H. Veeder, Monroe; Edward A. Flemming, Queens; Henry J. Noerling, Columbia; Elias H. Bartley, Kings.

Reference Committee on the Reports of the Committee on Nursing and the Committee on Physical Therapy: John E. Jennings, Chairman, Kings; Sylvester C. Clemans, Fulton, Lyman C. Lewis, Allegany, Edwin H. Fiske, Kings, Adelbert Allen, New York.

Reference Committee on the Report of the Committee to Form a Plan to make Toxin Anti-toxin available to Every Child in the State: Alec Thomson, Chairman, Kings; Brayton E. Kinne, Albany; Louis A. Friedman, Bronx; Francis M. O'Gorman, Erie; Frederick J. Bowen, Livingston.

Reference Committee on Credentials: The Secretary.

Reference Committee on New Business A: Edward M. Colie, Jr., Chairman, New York; George A. Leitner, Rockland; Edwin A. Griffin, Kings; Morris Maslon, Warren; George M. Cady, Tioga.

Reference Committee on New Business B: Samuel J. Kopetzky, Chairman, New York; Hyzer W. Jones, Oneida; W. Grant Cooper, St. Lawrence; Edwin C Podvin, Bronx; Howard C. Murray, Herkimer.

Reference Committee on New Business C: David J. Kaliski, Chairman, New York; Charles E. Scofield, Kings; Thomas P. Farmer, Onondaga; George S. Towne, Saratoga: Lucius H. Smith, Wayne.

The Speaker: I shall now ask the various Committees to proceed to their respective duties.

4. Unfinished Business

The Speaker: The next order of business is unfinished business arising from the proceedings of the last House of Delegates. Mr. Secretary, is there anything on your desk?

The Secretary: There is not.

The Speaker: We shall now proceed to new business.

5. Address of the President

The Speaker: The next order of business is the address of the President.

The Secretary: Owing to the fact that this report appeared in the May 1, 1931, issue of the New York State Journal of Medicine, and is in the hands of the delegates, I would ask the privilege of moving that it be referred, without reading to the proper reference committee.

Motion seconded and carried.

The Speaker: The next order of business will be the reports of the various officers and committees, including the Council, Trustees, Board of Censors, Secretary,

Treasurer, Councillors, and the standing and special committees

6 ANNUAL REPORTS

The Secretary moved that as all the reports have been printed in the May first issue of the *Journal* and also have been distributed to the delegates, they be referred to the respective reference committees as printed

Motion seconded and carried

7 TOXIN-ANTITOXIN COMMITTEE

Dr Van Etten, of the Bronx Presented the following resolution

As chairman of the Committees to make Toxin Antitoxin available to every child in the State, I recommend that this Committee be discharged—for the reason that the five year campaign period has expired and for the additional reason that this work now lies within the field of the Committee on Public Health and Medical Education

I further recommend that consideration of the subject of preventive immunizations be referred to the Committee on Public Health and Medical Education

The Speaker Referred to the proper committee (Sec 50)

8 CREDENTIALS

The Secretary Mr Speaker, before this meeting continues I would like to have you decide a question I have in my hand a telegram which reads 'I hereby authorize John H Reid to act as delegate for me Haskell" Dr Haskell's alternate Dr Reid, has never been elected by his County Society, Rensselaer County As Chairman of the Credentials Committee I naturally have to decide, but I would rather have the decision come from the Speaker (See Sec 1 and 49)

The Speaker Part of the rule is that a delegate must present credentials signed by the President and Secretary of his respective County Society, and that will be my ruling I would be very glad to have Dr Reid sit in the House of Delegates, but I am afraid I will have to deny him a vote

9 VOLSTEAD ACT IN RELATION TO PHYSICIANS

Dr Sondern of New York Presented the following resolution

WHEREAS, Congress has undertaken to fix the dose of wine, whiskey and brandy by legislative fiat, thus taking over the functions of pharmacologists and physicians and

WHEREAS, the Volstead Act compels physicians to betray the confidences of their patients by keeping a record of their diseases and ailments which records are open for inspection by the Federal Prohibition Authorities, thus violating the traditions of the medical profession medical ethics and the laws of a number of our states, and

WHEREAS, relief from these conditions has been sought in the courts and has been denied by the United States Supreme Court, and

WHEREAS the Wickersham Commission has unanimously made the recommendation "Removal of the causes of irritation and resentment on the part of the Medical Profession by (a) Doing away with the statutory fixing of the amount which may be prescribed and the number of prescriptions (b) Abolition of the requirements of specifying the ailment for which liquor is prescribed in the book to go into the public files, (c) Leaving as much as is possible to regulation rather than by fixing details by statute,'

Now, THEREFORE, BE IT RESOLVED, that the Medical Society of the State of New York hereby formally expresses its disapproval of those portions of the Volstead Act which invade the right of the State of New York to regulate the practice of medicine within its own borders and which deprives the physician of his right to the free exercise of his judgment in the practice of his profession,

AND BE IT RESOLVED that the Medical Society of the State of New York demand of Congress the repeal of said portions of the Volstead Act,

AND BE IT RESOLVED that the Medical Society of the State of New York urge each of its members to demand of his senators and congressmen the repeal of said portions of the Volstead Act

AND BE IT RESOLVED, that the Secretary of the Medical Society of the State of New York be and hereby is instructed to transmit a copy of these resolutions to the Senators from New York and to each representative in Congress of the State of New York,

AND BE IT FURTHER RESOLVED, that the Delegates of the Medical Society of the State of New York to the House of Delegates of the American Medical Association be and hereby are instructed to present a similar resolution to the House of Delegates of the American Medical Society at its next meeting for action

The Speaker Referred to Reference Committee on New Business A (Section 75)

10 MEDICAL PUBLICITY COMMITTEE

The Secretary I have a report of the special committee appointed to study the letter from Dr H A Houghton in regard to authorizing medical publicity It has examined this question from many angles, including that section of the President's Annual Report for 1930 in which the subject was partially dealt with It would respectfully report as follows

(1) That the necessity of an outlet from the State Society through some committee of editorials and lay medical articles seems advisable, and ways and means should be discussed in the House of Delegates as to the advisability of creating (a) a regular standing committee for such purposes, by proper amendments to the Constitution, which would apparently take too long to start a project or (b) creating a sub committee under the direction of the present Publication Committee with power given them and with an appropriation to engage a physician in part time or full time to formulate and publish such articles, as seem pertinent, in the newspapers and lay magazines, such as are published by the group headed by the Editor of the *A M A* Journal

Dr Houghton's letter is appended hereto for study by the reference committee to which this report may be referred, as it is the hope of your Special Committee that the subject may be referred by the Executive Committee to the House of Delegates—and there brought forth for full and free discussion, that the various Delegates may take back to their Component County Societies the results of the discussion

Respectfully submitted
JAMES N VANDER VEER *Chairman*

The Speaker Referred to Reference Committee on New Business B (Section 51)

11 PRESS RELATIONS COMMITTEE

Dr Heyd presented the following resolution

WHEREAS it is desirable to provide the press with authentic medical news and place the views of the organized profession before the public and

WHEREAS, the interests of public health education frequently demand that individual physicians broadcast over the radio on medical topics or write for lay magazines and newspapers, and

WHEREAS, it is necessary that copy of this type adhere to the highest standards and that the self-advertisement of publicity seekers within the profession and of quacks faddists and irregular practitioners without it be curtailed as far as possible,

THEREFORE BE IT RESOLVED, that the House of Delegates of the Medical Society of the State of New York

shall establish a Press Relations Committee to take these matters in charge and formulate rules and regulations to govern them, these rules to be submitted for approval to the House of Delegates or, ad interim to the Council or its Executive Committee and

BE IT FURTHER RESOLVED, that this Press Relations Committee shall embrace the entire state in its workings and shall be composed of two or more members from each District Branch of the Medical Society of the State of New York.

The Speaker: Referred to Reference Committee on New Business B. (Section 51.)

12. RETIREMENT FUND FOR PHYSICIANS

Dr. Patterson of New York: Presented the following resolution:

WHEREAS, no provision at present exists in the Medical Society of the State of New York for retirement stipends for physicians in the State of New York; and

WHEREAS, in certain other professions such provision has been successfully made; and

WHEREAS, it would seem advisable that the delegates here assembled should take appropriate action to this end,

BE IT THEREFORE RESOLVED, that the Medical Society of the State of New York through its delegates here assembled authorize the appointment of a Committee of not fewer than five to study ways and means of establishing a Retirement Fund for the benefit of the members of the Medical Society of the State of New York; and

BE IT FURTHER RESOLVED, that said Committee be prepared to make a report at the next regular meeting of this body.

The Speaker: Referred to Reference Committee on New Business C. (Section 99.)

13. CERTIFICATION OF SPECIALISTS

Dr. Trick of Erie: Presented the following resolution:

The Committee on the Certification of Specialists was appointed to carry out the recommendation adopted by this House in June of 1929.

The solution of this problem is a very difficult one and has been approached with the greatest caution.

At a meeting held in Albany in January, 1931, consisting of representatives from the Department of Education, Board of Medical Examiners, the Deans of the Medical Schools, the New York Academy of Medicine, and the Medical Society of the State of New York, the following resolution was adopted:

"That the Department of Education in conference with the Medical Society of the State of New York proceed to formulate plans for the preliminary education of specialists."

Shortly after the meeting a resolution to be presented to the House of Delegates of the American Medical Association was published in the bulletin of the American Medical Association. The principal point of the said resolution reads as follows:

"Resolved that the Speaker of the House of Delegates shall appoint by and with the advice of the President and the Board of Trustees a Commission on qualifications for specialists composed of nine members; that the said Commission shall undertake to define the qualifications that should be required of the individual physician who desires to limit his practice to any special field and to be known as a specialist, and that in arriving at such definition the Commission on Qualifications for Specialists should give consideration to questions of education, training, and clinical experience."

That this Committee be enlarged as may seem necessary or desirable; that an appropriation for the expenses of this Committee be included in the budget; that this Committee continue to carry out the intent of the resolution adopted in January in conformity with the work of the Commission of the American Medical Association, if it should be appointed.

We would recommend that a special committee on the certification of specialists be created.

The Speaker: Referred to Reference Committee on New Business B. (Section 52.)

14. MINIMUM WAGE FOR PHYSICIANS

The following resolution introduced by Dr. Julius Ferber of New York was read by Dr. Messing of New York.

WHEREAS, the Medical Society of the County of New York after considerable study of the exploitation of physicians by municipal and state departments as well as by lay corporations saw fit to endorse the movement, to demand the five dollar minimum wage per hour for physicians employed on part time, and

WHEREAS, because of the economic distress now prevailing generally forces many physicians to accept a part time position at lesser rate,

THEREFORE, BE IT RESOLVED, that the House of Delegates of the Medical Society of the State of New York record its opinion in favor of a minimum wage of five dollars per hour for physicians working upon a part time basis, but

BE IT FURTHER RESOLVED, that a five dollar per hour minimum charge shall not be so construed as a demand for an increase in salary for medical men employed in regular positions under the Civil Service Laws, nor for physicians holding regular departmental positions which after a term of service entitle the holder thereof to a pension.

The Speaker: Referred to Reference Committee on New Business A. (Section 73.)

15. RECOGNITION OF PHYSICIANS IN FOREIGN COUNTRIES

The following resolution was presented by Dr. Kopetzky of New York.

WHEREAS, many foreign countries do not recognize medical diplomas granted in the United States and do not permit American doctors, graduates of American Medical Colleges to practice, and

THEREFORE, BE IT RESOLVED, that the House of Delegates of the Medical Society of the State of New York instruct its delegates to the American Medical Association to bring this situation to the attention of the House of Delegates of the American Medical Association for the purpose and to the end that this unjustified disqualification of graduates of medical schools of the United States be discontinued and that American physicians desiring to practice in foreign countries be granted the same rights and privileges as their nationals have in the United States.

The Speaker: Referred to Reference Committee on New Business C. (Section 100.)

16. PRIVILEGE OF THE ASSEMBLY ROOM

The presence in the House of a gentleman who had drawn up and supported a bill adverse to the interests of the medical profession and the welfare of the public, having been brought to the attention of the speaker, the speaker called for a vote on the question of whether the privilege of remaining in the room should be accorded to him. A vote was thereupon taken and it was decided unanimously in the negative. (See Section 123.)

17. RECIPROCITY IN RECOGNITION OF AMERICAN PHYSICIANS

Dr. Kopetzky, of New York: Presented the following resolution:

WHEREAS, many foreign countries do not recognize graduates of American Medical Schools, nor permit them to practice medicine,

THEREFORE, BE IT RESOLVED, by the House of Delegates of the Medical Society of the State of New York, that this situation be brought to the attention of the Regents of the State of New York for the purpose and to the end that some degree of reciprocity be established and that the existing discrimination against American doctors be stopped

The Speaker Referred to Reference Committee on New Business C (Section 100)

18 PAY CLINICS

Dr Subkis, of New York Presented the following resolution

WHEREAS, there is an increasing tendency on the part of Dispensaries and the Out Patient Departments of Hospitals and Medical Centers to conduct Pay Clinics, and

WHEREAS these Clinics diagnose and treat patients outside of the Provision of the New York State Dispensary Law,

THEREFORE BE IT RESOLVED, that the Committee on Legislation initiate legislation at the next session of the New York State Legislature to the effect of preventing Pay Clinics from being operated under dispensary laws

The Speaker Referred to Reference Committee on New Business C (Section 102)

19 MEDICAL PRACTICE BY CORPORATIONS

Dr Herber of New York Presented the following resolution

WHEREAS, the Judicial Council of the American Medical Association in its report as published in the American Medical Association Bulletin as of April 1931, regards the decision of Judge Samuel R Blake of the Superior Court of the State of California, in and for the County of Los Angeles, in a case of Granville McGowen, Plaintiff, vs Medical Service Corporation, a corporation, defendant as being of the greatest importance at a time when commercial organizations established for profit are engaging in the sale of medical service in a manner that may be detrimental to the public good and opposed to the progress of scientific medicine,

THEREFORE, BE IT RESOLVED, that the House of Delegates of the Medical Society of the State of New York instruct its counsel to bring suit against one of the medical agencies engaging as a corporation, in the practice of medicine, that this suit be pressed for a decision upon two fundamental questions (1) Can a corporation practice medicine? (2) Is the manner and method of the defendant corporation such as to constitute the practice of medicine?

The Speaker Referred to Reference Committee on New Business A (Section 74)

20 STATE COMMITTEE ON PUBLIC RELATIONS

Dr Donnelly Resolutions adopted by the Medical Society of the County of Erie May 18, 1931

WHEREAS the Report of the Chairman of the Committee on Public Relations of the Medical Society of the State of New York, published in the State Journal May 1, 1931, approved the development of State aided county hospitals, and

WHEREAS, State aided institutions for medical care bring such hospitals under the dominance of the State Department of Health and promote the advancement of State medicine, and

WHEREAS the Chairman of said Committee recommends in his report that county medical societies establish intimate contacts with the leaders of every volunteer health organization in the county and

WHEREAS, each county medical society can best determine for itself the needs of its own locality and the worth of local volunteer health organizations and foundations and

WHEREAS, the Chairman of said Committee has had intimate contact with the State Charities Aid Association, as shown by a previous report he made, and in his present report seeks to impress organized medicine with the viewpoints of such volunteer organizations as the State Charities Aid Association whose record and activities are contrary to the economic welfare of the medical profession, and

WHEREAS, in 1930 the Trustees approved an appropriation of $2,500, to promote the work of the Committee on Public Relations,

THEREFORE BE IT RESOLVED, that the Medical Society of the County of Erie at a stated meeting May 18, 1931, records its disapproval of the report of the State Committee on Public Relations on the ground that it seeks to advance State medicine and to promote the encroachments of lay health organizations and foundations in the field of organized medicine

RESOLVED, that the Committee on Public Relations requires an entire new personnel which shall not be chosen from physicians who are associated with the State Charities Aid Association or its affiliated bodies

RESOLVED, that the Medical Society of the County of Erie requests the Executive Committee of the State Society in preparing the budget for the coming year to discontinue the annual appropriation of the funds of the Society for the work of the Committee on Public Relations

RESOLVED, that the Medical Society of the County of Erie requests that the amount of money appropriated in 1930 to the Committee on Public Relations be added to the appropriation made for the work of a committee more useful to the medical profession and recommends in particular the Committee on Legislation

The Speaker Referred to the Reference Committee on the Report of the Committee on Public Relations (Section 21) (No action taken)

21 PRELIMINARY PREPARATION OF FUTURE RESOLUTIONS

Dr James Smith of New York Presented the following resolution

WHEREAS the House of Delegates of the Medical Society of the State of New York transacts business by means of resolutions brought before it by the delegates, and

WHEREAS some of these resolutions are of the greatest importance to the medical profession and therefore require study and deliberation on the part of the profession and of the delegates who are to vote on these resolutions,

THEREFORE BE IT RESOLVED, that it is the sense of the House of Delegates of the Medical Society of the State of New York that most resolutions to be brought before this House should be in the hands of the Secretary not later than twenty days before the date of the Annual Meeting of the House of Delegates, and that such resolutions be printed in the May 15th issue of the NEW YORK STATE JOURNAL OF MEDICINE

The Speaker Referred to Reference Committee on New Business C (Section 56)

22 COUNTY DEPARTMENTS OF HEALTH

Dr Leone of Erie Presented the following resolution

RESOLVED, that the House of Delegates declare itself opposed to any legislative bill to make compulsory the establishment of county boards of health or county health units

The Speaker Referred to Reference Committee on New Business C (Section 70)

23 OPTOMETRY LAW

Dr Leone of Erie Presented the following

RESOLVED that the Secretary of the State Medical Society obtain an opinion from the Legal Counsel for

the Society on the constitutionality of the amendment to the optometry law enacted in 1931.

The Speaker: Referred to Reference Committee on New Business C. (Section 71.)

24. Birth Control

Dr. Donnelly of Erie: Presented the following:

Resolved, that the House of Delegates declare its opposition to the introduction or enactment of any legislative bill that shall change the policy of the State of New York in the matter of birth control.

The Speaker: Referred to Reference Committee on New Business B. (Section 101.)

25. Medical Advisory Board to Labor Department

Dr. Donnelly of Erie County: Presented the following resolution:

Resolved, that the House of Delegates declare itself opposed to any legislative bill for the creation of a medical advisory board in the Department of Labor.

The Speaker: Referred to Reference Committee on New Business B. (Sections 54 and 58.)

26. Free Choice of Physician

Dr. Donnelly of Erie County: Presented the following resolution:

Resolved that the Medical Society of the State of New York, through its Committee on Legislation, urges the passage of an amendment to the Compensation Act empowering the injured employee to choose his own physician.

The Speaker: Referred to Reference Committee on New Business B. (Sections 53-57.)

27. Cultists' Legislative Bills

Dr. Donnelly of Erie: Presented the following resolution:

Resolved, that the Medical Society of the County of Erie pledges its whole-hearted support to assist the State Committee on Legislation in defeating cultists' bills by personal interviews with legislators from Erie County prior to the next election.

The Speaker: That will be referred to Reference Committee on New Business C. (Section 103.)

28. Sewage Disposal Plants

Dr. Donnelly of Erie: Presented the following resolution:

Resolved, that the House of Delegates declare itself opposed to any amendment to the law that shall centralize authority in the State Department of Health concerning the location and erection of sewage disposal plants for municipalities.

The Speaker: Referred to Reference Committee on New Business A. (Section 72.)

29. Special Committee on Free Choice of Physicians

Dr. Lyons of Erie: Presented the following resolution:

Whereas, at the 1930 session of the House of Delegates a motion was carried that a special committee be appointed composed of members who have declared themselves in favor of free choice of physicians in compensation cases for the purpose of unifying all interests, and

Whereas, an amendment to said motion was made and carried that it be with authority to make necessary provision for counsel, and

Whereas, the Medical Society of the County of Erie has received no information from any authorized source that said *Special Committee* created by vote of the House of Delegates had been appointed as required by Section 13 of Chapter X of the By-Laws of the State Society,

Therefore Be It Resolved, that a *Special Committee* be appointed composed of members who have declared themselves in favor of free choice of physicians in compensation cases with power to act in the several counties of the State for the purpose of unifying all interests in support of an amendment to the Workmen's Compensation Law which shall permit injured employees the privilege of selecting their physician.

Resolved, that each county medical society in the State shall be invited to recommend a volunteer representative from its members to be appointed to said committee and such volunteer member shall become Chairman of the County sub-committee should the County Medical Society see fit to increase the personnel of its sub-committee.

The Speaker: Referred to Reference Committee on New Business B. (Section 55.)

30. Restraint on County Societies

Dr. Garen of Cattaraugus: Presented the following resolution:

Resolved, that it is the sentiment of the House of Delegates of the Medical Society of the State of New York that its members or committees shall not be permitted to engage in the promotion of a medical project, state or national, requiring legislation until such project and the proposed legislation thereon shall have been submitted for consideration to the House of Delegates and approved by a two-thirds vote.

30A. Acceptance of Subsidies

Dr. Garen also introduced the following resolution:

Resolved, that no member of this Society or committee of this Society shall be permitted to accept funds, grants, donations or any form of financial assistance either directly or indirectly from personal or lay sources for the promotion of medical projects requiring legislation without permission from the House of Delegates by a two-thirds vote.

The Speaker: Both these resolutions referred to Reference Committee on New Business A. (Sections 68 and 69.)

Are there any other resolutions under the head of new business to come before the House of Delegates?

Are there any committees ready to report?

The Reference Committee on the Report of the President I believe is ready to report.

31. Report of the President

Dr. Warren: The Committee wishes to express the pleasure it has had in studying our President's report. (Journal May 1, 1931, page 517). The report speaks first of the work done; a tremendous work that could only have been accomplished by one of unselfish devotion to the cause. The report shows that our President was approaching his duties through the idealisms of medicine and attempting constantly to understand through its work the present difficulties of our profession with the idea of formulating principles, not policies or politics, to guide us correctly in their attempted solutions.

Your committee wishes to emphasize that the report commonly deals in principles and as such shows the understanding of our leader in first settling the principle upon which proper action must be built if proper results are to be gotten. His unusual ability in analyzing the factors causing some of our present difficulties and his clear conception as to their solution have brought much commendation, not only from our own state but from medical organizations in a great number of states in which he has participated in programs speaking on the relationships of medicine.

Your committee furthermore requests that every member of this House before passing his vote on recommendations should ask himself what is best in this instance for medicine. The time has come when the

"I", the personal angle and the local factional attitude must be submerged for the good of the whole. It must be further remembered that although technically the responsibility of this body ends in the Medical Society of the State of New York still the actions of this Society are discussed and copied by many others and hence our responsibility to our action does not end here. To lead others however, we must approach our problems with a judicious mind—we must have facts—and to gather facts we must work.

Your committee speaks as it has of the work and spirit of our President in which we are sure that every member of this House agrees, and it now wishes to pass to the recommendations under the President's report.

Mr. Speaker, I ask for your ruling as to whether the report will be read in toto before the recommendations are passed on, or whether it will be acted on separately?

The Speaker: I think we will act on each recommendation separately and then on the report as a whole.

Dr. Warren: Your committee has taken up each of the divisions as mentioned in the President's Report and in its report will follow that detail.

The report, deals first with the President's activities—which has been covered in general by your committee in its introductory remarks. (Jour. May 1. p. 517.)

The report refers to some of medicine's difficulties of the past,—but, through common sense and statesmanship—applied to her problems—she has emerged successfully and progressed favorably.

It calls for the application of the same principles of action to meet our present day problems.

And your committee approves of this section of the report.

I move the adoption of this recommendation.

Motion seconded and carried.

32. A Journal Reporter in Every County Society

Dr. Warren: The President refers to the constant effort which has been made in the past to make our Journal the real mouthpiece of our Society. (Jour. May 1, p. 518). This effort must be continued. To constantly improve it, means more interest must be given to it. To this end the committee recommends:

(1) That the House of Delegates instruct each County Medical Society to appoint or elect a reporter whose duty shall be to report to the Journal the results of meetings and activities of his Society. This reporter may or may not be the secretary of the County Society.

I move the adoption of this recommendation.

The Speaker: I ask the Committee to revise that portion of their report in which they say "That the House of Delegates instruct the County Societies." The House of Delegates cannot instruct the County Societies, they can advise them. The County Societies have a government of their own.

Dr. Warren: We will accept that.

Dr. Leone of Erie: I have before me here the comment in the Report of the President wherein he states the Journal is designed and maintained in order to affect all the activities of the State Societies and to give a résumé of the trend of medical public opinion.

Now, to me, as nearly as I can understand it, that is practically laying down a new principle as far as it concerns this State Journal. In that short paragraph, very concise, but very important, our President has entirely ignored the activities of the various component County Societies. It seems to me that that is not only a new principle that he has just announced, but it also is a violation of that part of our By-Laws wherein it is stated that the Journal shall publish anything that comes from the County Societies. Now, this past year I have had occasion to peruse it very carefully and I find where a great number of the County Societies have been entirely ignored in having access to the columns of the Journal; particularly is it so concerning the activities that have been carried on by the County of Erie. We have repeatedly sent articles, perhaps sometimes not to the liking of our brethren, but by an unforeseen plan our whole scheme of publication and articles has been entirely ignored so far. We have not heard anything from them. I do not see the reason for it. It seems to me according to the By-Laws and Constitution of this Society the component County Societies are part of it, and I cannot understand why they should be so ignored. It seems to me they ought to be included in the great scheme of this Federation of County Societies and we should have some consideration in the use of the Journal.

Dr. Wightman stated that such news as came to the State Journal and was acceptable to the members had been freely published and that there had been no discrimination against any County Society; that the Journal published what was sent them. He also stated that the Journal was not partisan in any form or shape, and that it would welcome anything that is new.

The motion for the adoption of this portion of the report was seconded and carried.

33. Bulletins of County Societies

Dr. Warren: The Committee further recommends that the sending of bulletins to the officers of the County Societies be approved when in the judgment of any committee it is necessary, but only after approval of the House of Delegates or the Council or the Executive Committee. (Jour. May 1, p. 518.)

I move the adoption of this recommendation.

Motion was seconded and carried.

34. Popular Medical Publicity

Dr. Warren: Again it recommends that the popular medical publicity now handled by the State Department of Health be approved and that the Department be requested to continue. (Jour. May 1, p. 518.)

I move the adoption of this recommendation.

Motion seconded and carried.

35. Graduate Education

Dr. Warren: The report next deals with graduate education, and advises that the subject of graduate education be given most careful consideration with the object of expanding it to the fullest practical limit. (Jour. May 1, p. 518.) Your committee commends the past efforts of this committee on graduate education which has formulated a program yielding invaluable benefit to the members of our society and fully recognizes that graduate education is one of the strongest means we have in getting our profession out of some of its difficulties and recommends that:

The Committee on graduate education should particularly sponsor those courses having a practical clinical bearing applicable to the work of the man in daily practice.

I move the adoption of this recommendation.

Motion seconded and carried.

Dr. Warren: It further recommends that the Committee on graduate education study the causes of poor attendance to graduate lectures to gain facts as to how this work can be more interestedly and successfully carried on.

It further recommends that the committee on graduate education hold conferences with the representatives of the medical schools of the State of New York with the idea of working out some possible program in which these schools will wholeheartedly cooperate.

I move the adoption of these recommendations.

Motion seconded and carried.

36. Economics Committee

Dr. Warren: Your committee recommends that the report of the Economics Committee bearing on the agree-

The Speaker: Permit me to inform you you are now voting on Dr. Garen's amendment.

The motion eliminating the words "Council or Executive Committee" was carried.

Dr. Rooney: I move to amend, that the date in this resolution be fixed as January 1, 1932; secondly, that prior to any action by any of the bodies of this society, a complete copy of the report of the Committee studying the recommendations of the so-called Health Commission shall be submitted to each component County Society in this state.

Motion seconded.

Dr. Ludlum offered an additional amendment that a referendum vote of the entire membership of the State Society be taken.

Dr. Rooney stated that he could not accept the amendment to his amendment inasmuch as the expenditure would be too great.

Dr. Bonnar withdrew his motion for a referendum in view of Dr. Rooney's explanation of the expense involved.

Dr. Winslow: I would like to ask Dr. Warren if he would be willing to accept Dr. Rooney's amendment?

Dr. Warren: If the other members of this Committee will so signify we will accept that amendment.

The amendment was accepted by the Committee.

The Speaker: The recommendation is that the House of Delegates instruct the Committee on Public Health and the Committee on Public Relations to study this report and make recommendations on all or any of the subjects presented and that such Committees report their recommendations to the House of Delegates not later than January 1, 1932.

The recommendation was carried.

Dr. Ludlum: As a point of information, how are they going to report to the House of Delegates?

The Speaker: That will be left to the Secretary.

The Secretary: I wish to rise on a point of information. I would like to know whether the House wants me to call a special meeting of the House of Delegates.

Dr. Ludlum: If I may be allowed to speak further, I move the report of the House of Delegates be in the form of a referendum vote.

Motion seconded.

Dr. Rooney: I move to amend Dr. Ludlum's motion in that this report will in the natural course of events be submitted to the Council, that if the Council determines that a special meeting of the House of Delegates is necessary, they shall call one or submit the question by referendum.

The Speaker: The amendment to the amendment of the resolution is that when this report is submitted, if the Council sees fit they may call a special meeting of the House of Delegates or take a referendum vote of the House of Delegates.

The amendment to the amendment was carried.

The Speaker: Now the amended resolution, or the amendment to the resolution which was acceptable to the committee is before you.

The recommendation is that the House of Delegates instruct the Committee on Public Health and the Committee on Public Relations to study the Report of the Governor's Commission, and to make recommendations upon all or any of the subjects presented and that the said committee report their recommendations to the House of Delegates not later than January 1, 1932, and that the Council in its wisdom refer this to the House of Delegates either by a special meeting or by referendum of the House.

Dr. Rooney: I regret again to take up the time of this House, but I feel there was one item the Speaker omitted. Prior to any action by the House of Delegates a copy of the report shall be submitted to each component County Society.

The Speaker: You are correct.

The recommendation was thereupon carried.

Dr. Warren: By way of explanation, our first recommendations only had to deal with the study of the volume that was printed to see whether we believed it merits some thought or action or some adjustment on the twelve subjects of the Commission's study.

The second recommendation is: Your Committee further recommends that the House of Delegates instruct the Committee on Public Health and the Committee on Legislation to study the report of the Special Health Commission and recommend such legislation as it deems necessary to carry out the recommendations of our Public Health Committee and our Committee on Public Relations, and to report to the House of Delegates or the Council or the Executive Committee not later than December 1st, 1931.

Dr. Rooney: I move that this recommendation be laid on the table. It is unnecessary. The Committee on Legislation is the official body of the Society and all legislation must be in accordance with the Constitution and By-Laws submitted through it and it will have the final say in the matter.

The Speaker: A motion is made that this part of the report be laid on the table.

Motion seconded and carried.

42. The Public Welfare Law

Dr. Warren: The report next speaks of the Public Welfare Law and its effective workings in certain counties of the state. (Jour., May 1, p. 521). It states that very few counties are taking advantage of this law and believes that it deserves wider usage and should be better understood. Your committee, therefore recommends; that the House of Delegates instruct the President of each county society as to the uses, benefits and the administration of the Public Welfare Law.

I move the adoption of the Report.

The Secretary: A point of information as to the portion "That the House of Delegates instruct the President of each county society as to the uses, benefits and the administration of the Public Welfare Law." How shall this be done?

Dr. Rooney: I would like to move to amend that that portion of the Public Welfare Law that relates to the Medical Profession be abstracted by the secretary of the Society and be published in the Journal.

Motion seconded.

The Speaker: You are now voting on the amendment that that portion of the Public Welfare Law which affects physicians be abstracted from the Public Welfare Law and sent by the Secretary's office to the various presidents of the County Societies.

Dr. Rooney: Since making my motion I have received information that copies of the Welfare Law have been sent to the Council and the Executice Committee, and that a copy can be procured free of charge from the Legislature. I therefore take the privilege of withdrawing my motion.

The Speaker: All in favor of that portion of the Reference Committee's report on the President's report, will signify by saying "aye." Contrary minded "no." The chair is in doubt.

All in favor of that portion of the report, or the recommendation of that portion of the report will please signify by standing.

Those opposed please signify by standing.

A rising vote was taken and the motion lost.

43. The Committee on Activities

We all recognize that frequent meetings and conferences of individuals interested in the same project yield much, but we also recognize that there must be no duplication for several reasons; expense, confusion in effort, and misunderstanding. (Jour., May 1, p. 521). Hence we believe that it would be best at present to use the machinery we now have to get the chairmen of com-

mittees together for conference This can be accomplished moderately well without added expense or change in By-Laws Hence, the committee suggests, that at those times when the council meets, the chairman of the Standing Committees can be gotten together for discussion of such problems as have a common interest

I move the adoption of this recommendation

Motion seconded and carried

44 THE TRUSTEES

Dr Warren The President recognizes that the Trustees really are the custodians of the Society and that that their function is to guard the trusts and properties of the society (Jour, May 1, p 521) They are men greatly interested in our organization They have served long and faithfully That they should always be informed of the activities of each chairman of the various standing and special committees seems to need no argument.

We, therefore, recommend that the monthly reports submitted by the chairmen of the various standing and special committees be duplicated and sent to each Trustee

I move the adoption of this recommendation

Motion seconded and carried

45 ORGANIZATION

Dr Warren The report of the President calls for a united front, particularly when dealing with the public (Jour, May 1, p 522) It recognizes debate as a proper means to attain a reasonable viewpoint It further recognizes that minority opinion is always helpful to keep majority rule from being too dictatorial, too dogmatic In these critical times your committee feels that divided opinions and multiple policies offer a great target for every volunteer or lay organization or individual who wishes to attack us We recognize that these thrusts are definitely harmful to us and to our profession in that they tend to break down the morale of our profession, and lessen public faith in our works After proper deliberation of our problems we should unitedly say—*This is the decision of medicine, of thinking medicine*—of organized medicine and not be rent by the prattle of disorganizing medicine With these facts in mind your committee recommends, that the House of Delegates approve in the principle of majority rule as determined after due deliberation, and expects each of its members to be loyal to the will of the majority when expressing his views on medical matters to the public

I move the adoption of this recommendation

Motion seconded and carried

46 MEDICAL CARE AND MEDICAL SERVICE

Dr Warren Your Committee well recognizes that this part of the President's report is a very important one (Jour, May 1, p 522) The people of the state must have both medical care and medical service available At present too few facts are known as to what is necessary to accomplish these ends and how many people will need some special provision for their care, and your committee recommends that a special committee of three be appointed the Chairman of the Public Health Committee, the Chairman of the Public Relations Committee and the Chairman of the Committee on Medical Economics, with the power to increase the personnel as necessary—to study the three questions on medical care and medical service as follows

1 What is proper and adequate medical service?

2 How can it be provided for all the people?

3 How can such service be adequately paid for? and that the committee report to the House of Delegates, the Council or the Executive Committee—either in a preliminary report—or serially or in toto as speedily as possible

I move the adoption of this recommendation

Seconded

Dr Rooney I move that this also lie on the table for the following reason

The Committee on Medical Care of the American Medical Association is just about completing their five year study on medical care and it is going to cover the whole United States of America

It seems to me that this will be an expensive duplication of effort by making another constituted group to carry on a study of this sort A report of that sort will probably be ready within a year, perhaps less, and as a member of this House, a member of the Board of Trustees, and as a member of your Committee on Medical Care, I move that this resolution lie on the table

Motion seconded and carried

47 APPRAISALS

Dr Warren The President's report recognizes that medical problems are not limited to New York State (Jour, May 1, p 523) They are nationwide They are worldwide They need study and more study—and every medical organization should be working alone some phase to help solve them Although our National body has done much along this line your Committee believes that the parent body should be very active in gathering facts through which we can appraise our own resources—to the end that such facts can be utilized in *adjusting our standards and improving our services* To this end the committee recommends that a resolution be presented to the American Medical Association at its 1931 meeting requesting that a national commission be appointed to make a study of the relationships of medicine to the public, to medical care, to medical service, and to all the interests of public health administration and practice for the purpose of developing constructive thought regarding them under the leadership of medicine and that this Commission be asked to make a *preliminary report with such recommendations as it may* have at the 1932 meeting of the American Medical Association with the object of bringing the influence of the organized medical profession to bear on every medical problem

I move the adoption of this recommendation

Motion seconded

Dr Rooney I move that this resolution lie on the table because the American Medical Association or its Council on Public Accounting and Public Relations has carried on this work constantly for a whole year and has for many years

Motion was seconded

The Speaker The motion is made and seconded that this portion of the report be laid on the table

Motion was carried

48 FUTURE POSITION OF MEDICINE

Dr Warren To one with a vision there are no difficulties They only serve to make one the better understand the problems Difficulties are capitalized by constructive action Reasonable men must finally meet on common ground and accept reasonable adjustments And so the writer of our report sees a very bright future through the leadership of medical statesmen who always arise in time of approaching storm and who through ability, devotion and principle get us through to greater usefulness So your committee heartily approves this spirit of the President who has the past year buried the "I" and lived for the issues of medicine (Jour May 1, p 523)

Motion seconded

The Speaker The motion is made that the report of the Committee be adopted as a whole of course with the various amendments that have been passed by the House

Motion seconded and carried

49. Credentials

The Speaker: I wish to announce that Dr. John H. Reid has produced sufficient credentials from his County Society and he is duly seated as a delegate from Rensselaer County. (See Secs. 1 and 8).

The Vice Speaker here took the chair.

The Vice Speaker: Are there any other Committees ready to report?

50. Report of Reference Committee on Toxin Anti-toxin

Dr. Thomson: Your Reference Committee appointed to consider the Report of the *Committee to Form a Plan to Make Toxin Anti-toxin Available to Every Child in the State* found no recommendation in the original report. (Jour., May 1, p. 564). While it was in session a supplemental report was received from the chairman of the committee reading as follows (Sec. 7): "As chairman of the Committee to make Toxin Anti-toxin available to every child in the State. I recommend that this Committee be discharged—for the reason that the five year compaign period has expired and for the additional reason that this work now lies within the field of the Committee on Public Health and Medical Education.

"I further recommend that consideration of the subject of preventive immunizations be referred to the Committee on Public Health and Medical Education.

Nathan B. Van Etten, *Chairman.*"

Your Reference Committee appreciates the point of view expressed in the Report—namely that the medical profession has not assumed the degree of leadership in the diphtheria elimination campaign which might be considered adequate.

On the other hand, your Reference Committee understands that in certain communities a great deal of immunization work has been done through the activities of the individual physicians and Medical Societies. It seems obvious to your Reference Committee that the Committee is correct in its comment that each County Society should assume as an important part of its public health program the continuous stimulation of its members to take a progressive attitude toward the elimination of a preventable disease.

Your Reference Committee further believes that the best way for the Medical Society of the State of New York to promote the prevention of diphtheria would be through the Committee on Public Health and Medical Education, and therefore concurs in the thoughts expressed in the supplemental report, and recommends that the special Committee be discharged with thanks, that the problem of diphtheria prevention be referred to the Committee on Public Health and Medical Education with instruction to evaluate the work done in the State through the County Societies, and present a suggestive plan, the principles of which could be adopted by each County Medical Society.

I move the adoption of the Report.

Motion seconded and carried.

51. Press Relations

Dr. Kopetzky: Your Reference Committee on New Business B has had presented to it two resolutions bearing upon the question of establishing a statewide press relations committee, the resolution introduced by New York County, and the one presented by Messrs. Vander Veer, Goodrich, and Trick (Sections 10 and 11). The resolution submitted by the latter three gentlemen works out the details of a press relations committee and bureau. The one submitted by New York County is a fundamental resolution and creates such a committee, tells its composition, and permits the committee to work its own details. We therefore recommend the adoption of the resolution submitted by the delegate from New York County. (Resolution A) And further recommend that the details contained in communication B be referred to this newly created committee for its study and recommendation.

I move the adoption of this recommendation.

Motion seconded and carried.

52. Certification of Specialists

Dr. Kopetzky: A resolution was introduced by Drs. Charles Gordon Heyd and Henry R. Trick which recommended that a special committee be created by this House of Delegates on "The Certification of Specialists." (Sec. 13). The committee feels that the time is approaching when the public will be entitled to know that a given physician has achieved the minimum requirements deemed necessary to hold himself out as a specialist; and we believe that the establishment of such a committee will be a step in the right direction. This Committee, after studying the question, and reporting upon it will afford this House of Delegates an ample opportunity for the full discussion of the details of the question later. In making this report, we again warn the House of Delegates that we believe it inadvisable to recommend anything that will bring the Medical Practice Act into question in the Legislature.

I move the adoption of this recommendation.

Motion seconded and carried.

53. Free Choice of Physicians

Dr. Kopetzky: We have received a resolution from Erie County "Resolved that the Medical Society of the State of New York through its Committee on Legislation urges the passage of an amendment to the compensation Acts empowering the injured employee to choose his own physician." (Secs. 26 and 57).

The committee approves this resolution, but does not think it necessary that it be passed by this House since this is the position of the House of Delegates of this Society. (Sec. 57).

54. Medical Advisory Board to Department of Labor

Erie County presented the resolution "That the House of Delegates declare itself opposed to any legislative bill for the creation of a Medical advisory board in the Department of Labor." (Secs. 25 and 58).

The Committee feels that a resolution of this kind is unwise and impolitic, because it ties the hands of the House of Delegates on a negative phase of a question. It is conceivable that an advisory committee might be devised by some legislator which would meet the approval of even Erie County, and if the resolution presented would be passed a county would have tied its own hands. We disapprove the resolution.

55. Special Committee on Free Choice of Physicians

The resolution introduced by Dr. Leone of Erie County (Sec. 29), that a special committee be appointed, composed of members who have declared themselves in favor of free choice of physicians in compensation cases with power to act in the several counties of the State for the purpose of unifying all interests in support of an amendment to the Workmen's Compensation Law, which shall permit the injured employee the privilege of selecting their physician, and to have added to it a volunteer representative who shall become the county sub-committee's chairman, is disapproved by this committee, because it sets up machinery on a single principle which is cumbersome, in conflict with existing machinery of the State Society, for example, the Legislative Committee, the Public Relations Committee, etc.

This Committee has already approved a resolution embodying the question of free choice and the State Society is on record favoring free choice of physicians by injured employees. It is therefore unnecessary to have a committee for propaganda purposes since the House

of Delegates is a unit and has acted as a unit on this question for a long time

56 PRELIMINARY PREPARATION OF FUTURE RESOLUTIONS

Dr Kopetzky The committee approves the resolution introduced by Dr Smith of New York County (Sec 21), and recommends that Resolutions to be acted upon by the House of Delegates shall be sent to the secretary of the Medical Society of the State of New York in ample time for publication in the May 15th issue of the NEW YORK STATE JOURNAL OF MEDICINE. This resolution, however should not be interpreted to preclude the introduction of resolutions from the floor of the House at the time of meeting of the House of Delegates, where the introduction of said resolution would have been impossible as above outlined

In other words, while we approve the preconvention publication of as many resolutions as possible so that the intelligence of the House of Delegates shall manifest itself in the action taken we would not set up a machinery which would preclude any man from the exercise of his right as a delegate of his county from introducing a resolution at the House of Delegates which could not have been sent because of some reason inherent in itself before the May 15th issue of the State Journal of Medicine

I move the adoption of this resolution

The Secretary The resolution requires the publication on May 15th, and that is rather impractical We may have a meeting of this House on April 20th What would become of the resolution then? We have had meetings of the House of Delegates in April

Dr Wightman Inasmuch as the desire of this recommendation is to inform every member of the State Society in ample time to consider a resolution will Dr Kopetzky accept a thirty day period previous to the meeting as ample time?

Dr Kopetzky We will

Dr Rooney I move to amend that this resolution shall not preclude the possibility of introduction of any resolution that has not hitherto been published at the meeting of the House of Delegates provided that twenty-five per cent of the members of that House approve of the introduction of the resolution

Motion seconded

The Vice Speaker Dr Rooney has stated that he moves to amend this resolution that this shall not be construed to preclude the introduction of resolutions of a delegate before this House provided twenty five per cent of the delegates have consented thereto All those in favor will signify by saying aye —opposed no

Amendment lost

Dr Kopetzky I move that the resolution with amendment be accepted by the Committee

Motion seconded and carried

Dr Kopetzky I now move the report of the Reference Committee on New Business B be adopted as a whole

The Vice Speaker It is customary to vote on each question individually

I would like to take them one at a time

Dr Kopetzky The first resolution is that this House of Delegates go on record again as favoring the free choice of physicians in compensation cases The committee feels that is not necessary because we are already on record but I think the House should take action on the recommendation of the committee The committee recommends that this be not adopted

Dr Bedell I do not believe that is the proper interpretation of the committee's action I would ask you sir, to have the Chairman of the Reference Committee make that statement so that we understand it is not that we disapprove we just do not wish to go on record again It is an unnecessary action I think that should be stated by the chairman

Dr Kopetzky Dr Bedell has exactly stressed the point I would be the last one to speak against the free choice of physicians I have fought for it for years I am in favor of it We feel we are on record and we weaken our position by restating it It is unnecessary to pass the same resolution again I do not know what to do with the resolution except the committee does not feel is should be passed

I move the recommendation of the Reference Committee be adopted

The Vice Speaker The motion is before the House that the Report of Reference Committee on new Business B be approved

Dr Leone, of Erie Do I understand you are including them all in one motion?

The Vice Speaker All in one motion

Dr Leone I move they be separated seconded and carried

The Vice Speaker Read the first resolution Dr Kopetzky

57 FREE CHOICE OF PHYSICIAN

Dr Kopetzky Resolved that the Medical Society of the State of New York through its Committee on Legislation urges the passage of an amendment to the Compensation Act empowering the injured employee to choose his own physician (Secs 26 and 53)

We take the stand of the State Society that it is unnecessary to pass it again

The Vice Speaker The question is the affirmation of the recommendation of the Committee on this matter

Motion seconded and carried

58 MEDICAL ADVISORY BOARD TO DEPARTMENT OF LABOR

Dr Kopetzky RESOLVED that the House of Delegates declares itself opposed to any legislative bill for the creation of a Medical advisory board in the Department of Labor (Secs 25 and 54)

Dr Rooney The recommendation of the committee as I understand it was that they disapproved of the resolution relating to a creation of a medical advisory board I do not recall the House has ever gone on record of approving or disapproving As I recall it the chairman of the committee said that their only desire to disapprove the resolution was in order to leave the House free to take such action afterward as they were disposed to take

For that reason and to clarify and dispose of the situation amicably I move this section of the report lie on the table

Motion was seconded and carried

Dr Kopetzky I move the adoption of the report as a whole with the exception of such parts as have been disposed of by motion to lay on the table

Motion seconded and carried

The Speaker resumed the chair

The Speaker Are there any other committees ready to report?

59 COMMITTEE ON LEGISLATION

Dr Ludlum Before proceeding to detailed consideration of this report your Reference Committee on the Report of the Committee on Legislation (Journal May 1 p 550) would re emphasize the very strenuous character of the work of the Standing Committee and call attention to the difficulty of its duties and the efficiency with which they have been performed Without any question this Committee deserves the hearty thanks of this House of Delegates and of the entire membership of the State Society and we recommend that the House of Delegates express this thanks by vote

I move the adoption of this recommendation

Motion seconded and carried

Dr Ludlum We quote an item of some interest in reference to legislative difficulties (N Y Med Week May 2, 1931)

"The Osteopathic Bill was passed in the Senate on a quick roll call. This may be attributed to the activities of Dr. Downing, the former Deputy Commissioner of the State Department of Education. During his incumbency of this office, especially while the battle for the Medical Practice Act was on, we heard much of his efforts on behalf of the practice of medicine in New York State. At the session of the Legislature he made a valiant effort to put the Osteopathic Bill of Senator Fearon and Assemblyman Tellier over."

60. Contact between Legislative Committee and Membership

Dr. Ludlum: "*Recommendation* 1 (*Jour.*, May 1, p. 550). Each and every County Society should establish a direct contact between the chairman of the legislative committee and the membership, through its secretary.

"In case of emergency the chairman of the County Legislative Committee should be given the power to call directly on the membership for letters, telegrams or telephones to the legislators at the expense of the Society."

The Reference Committee sees, in connection with this recommendation, that it would be necessary for each county society to limit the amount of expenditure allowed, but this does not need to be included in the recommendation and the Reference Committee approves this recommendation and moves its adoption.

Motion seconded and carried.

61. Study of Records of Legislators

Dr. Ludlum: "*Recommendation* 2 (*Jour.*, May 1, p. 550). That each and every County Society study the records of their respective legislators in relation to the practice of medicine and take effective action through the local press and personal propaganda to prevent the re-nomination and election of those who are avowedly hostile to their interest."

I move the adoption of this recommendation.

Motion seconded and carried.

62. Obedience to Decisions of the House of Delegates

Dr. Ludlum: "*Recommendation* 3 (*Jour.*, May 1, p. 551). That the House of Delegates call the attention of the County Societies that as members of the State Society it is their duty to abide by the decisions of the House of Delegates, and the House of Delegates instruct County Societies that all matters of legislation be transacted through the State Legislative Committee."

Literally interpreted this note of instruction that "all matters of legislation be transacted through the State Legislative Committee" would minimize the influence of County Societies over their legislators to the vanishing point and we would offer as a substitute: That the House of Delegates call the attention of the County Societies to the fact that it is their duty to abide by the decisions of the House of Delegates and more specifically as expressed in the sentence in the By-laws which reads: "The component County Societies and their committees on legislation shall cooperate with this Committee and act in harmony with it on all such matters."

I move the adoption of the recommendation.

Motion seconded.

Dr. Leone of Erie: It seems to me that in the adoption of this part of the recommendation, while it is good in some points, on the other hand it practically ties the hands of the County Societies so that they would not be able to do any effective work for or against any proposition.

We had a demonstration of that this past winter, and I think Erie County if they were to work through the State Legislative Committee would not have accomplished anything at all.

But, as matters stand, I believe we did accomplish something temporarily at least to see that this so-called Wicks-Hutchinson bill was not passed through the legislature.

For that reason I think you should make some changes not to tie the hands of the County Societies, so as to make them helpless.

Dr. James Smith of New York: Although I believe that in the past bulletins have been printed stating the names of those legislators who took a stand adverse to organized medicine, would I be out of order in requesting that this list of those gentlemen be published again in our Medical Journal so that we may refresh our minds before the next session?

Dr. Bonnar of Erie: In regard to the initiative of County Societies in legislative matters, personally I am distinctly in favor of the County Society acting quite independently, but in cooperation, too, with the State Committee on Legislation.

I do not believe we should in any way lessen the expression of any County Society on any matters of legislation, therefore in any way minimizing the relationship of the county in legislative matters. I am not in favor of it. I could not quite understand the reading of the resolution, but that is my attitude in regard to legislative matters.

Dr. Rooney of Albany: I do not think that the State Society has attempted in a legislative hearing to exclude any individual member from expressing his own individual opinion, but, I do not believe any individual member has the right to say he represents such a group unless he does actually represent his own County Society, and if he does he has a perfect right to appear before any legislative committee of this State under his constitutional privileges, as a citizen, and speak for what he pleases.

Now, I feel every chairman of every committee of this Society should not be required to introduce speakers who are opposed to the position of the State Society, but I believe that they should make absolutely no attempt to prevent them from speaking.

Dr. Sherwood of Niagara: The difficulty here seems to arise in connection with the late Wicks-Hutchinson Bill as a result of an apparently contradictory policy of the State Body in some of the provisions of that bill.

I think in that connection that it is no more than reasonable to expect the duly elected and created officers of the organization to define sharply between their personal opinions in connection with the proposed legislation and the official position of the State Society and House of Delegates.

It is not up to the different County Societies to take positions at legislative hearings in opposition to the policies of the State Society. However, in regard to these recommendations I would like to have the doctor make clear what provision was made in case the official position of the House of Delegates has not been made known.

For example, as far as I know the House of Delegates has taken no position regarding full time health officers in cities over 50,000. If I am wrong you may correct me.

If this resolution includes that contingency where the official position of the State Society has not been made known, I would be in favor of it.

Dr. Ludlum: I think I might clarify the situation by saying that neither the chairman of this Reference Committee nor this Reference Committee has anything to do with expressing its own opinion, nor has it anything to do with the general policy in this recommendation. The committee has merely called attention to the provision in the By-laws which is the legal document under which we now operate.

If that provision is not satisfactory this House of Delegates or any other House of Delegates through proper procedure may change that provision of the By-laws.

I move the adoption of this recommendation
Motion seconded and carried

63 Medical Publicity on Chiropractic

Dr Ludlum 'Recommendation 4 That a committee consisting of members of the State Society and the Academies of Buffalo, New York, Rochester, Syracuse and Utica be appointed whose duties it shall be to acquaint the public by well prepared, repeated publicity—that it is to the public's vital interest to see that the practice of medicine is kept at the highest possible level, that the public should be more concerned in keeping out the quack and unfit than the medical profession, and that organized medicine is tired of fighting the public's fight single handed (*Jour* May 1, p 551)

That a committee consisting of members of the State Society and the Academies of Buffalo, New York, Rochester, Syracuse and Utica be appointed whose duty shall be to urge the following proposition on the presidents and faculties of the great universities of the State of New York

'If there is a grain of scientific truth in the theory of chiropractic, it is their duty to teach it If on the other hand, chiropractic is a fraud and has no foundation in truth, then it is the duty of the said universities to their respective communities and the people of the state—to come out and say so

That the universities be urged to appoint a group of non medical scientists to investigate and report on the theories and practice of chiropractic, and that, if necessary, the medical profession pay for the expense of the investigation"

Your Reference Committee sympathizes most sincerely with the state of mind which inspired the preparation of this recommendation and approves most heartily the general idea contained in it, but aside from disapproving matters of detail such as including in a committee of the State Society, persons designated otherwise than as members of its own body, it believes that in this House of Delegates or soon, the entire question of medical publicity will be considered and therefore it would recommend that this recommendation of the legislative committee be referred to the Council unless it be considered by this House of Delegates in connection with other matters of publicity

I move the adoption of this recommendation
Motion seconded and carried

64 Publishing Rules and Regulations of Sanitary Code

Dr Ludlum "Recommendation 5 That in the future the Public Health Council shall cause to be printed in Health News' all proposed rules and regulations and modifications of the sanitary code Before any such rules regulations and modifications shall be adopted, the Public Health Council shall announce not less than ten days in advance of the hearing a place and date not less than one month subsequent to the first publication of the proposed measures, where it will hear those who may have objections to the proposed measures" (*Jour*, May 1 p 552)

I move the adoption of this recommendation
Motion seconded and carried

Dr Ludlum The Committee on Legislation offers five recommendations

Your Reference Committee approves three of these and the principle involved in the other two, and so reports to you

Further, it has considered it a duty to add certain information to that contained in the report of the Committee on Legislation as well as to express its appreciation and approval of the work done by this Committee It recommends the adoption of the report
Seconded and carried

65 Medical Economics

Dr Stetten Your Reference Committee on the Report of the Committee on Medical Economics (*Jour*, May 1, p 553) has carefully considered this Report which deals exclusively with the proposed arbitration agreement to be entered into between the Medical Society of the State of New York and the Compensation Insurance Carriers The report as a whole, is approved, and its adoption recommended, with, however, the elimination of the appended fee schedule To replace this fee schedule it is recommended by your Reference Committee that such a schedule, because of geographical peculiarities in the several counties of the State, should be arranged separately between the individual counties and the insurance carriers as has been done in the County of New York It is also recommended by your Reference Committee that the Committee on Medical Economics be instructed to assist the individual counties of the State in arranging this fee schedule with the insurance carriers, along the lines indicated in its Report and that further the Committee on Medical Economics, be instructed to help the counties in whichever way possible in carrying out this arbitration agreement with the insurance carriers

I move the adoption of the Report

Dr Dyer of Broome stated that the attitude of the County Society of Broome was that this was absolutely useless, that it is redundant and merely a repetition of what already exists that it offers nothing, profits nothing and simply obscures the situation as it is He thereupon made a motion that the adoption of the report be tabled

Motion was seconded but not carried

The Speaker Remember gentlemen, the report of this committee does not include the adoption of a fee schedule It approves the recommendation of the Committee on Medical Economics with the exception of a fee schedule and provides the means of working that out.

I move the adoption of the Report
Seconded and carried

66 Nurse Problem

Dr Jennings Your Reference Committee on the Report of the Committee to study the nurse problem approves the report and deplores the existence of the conditions which it sets forth (*Jour*, May 1, p 563)

We approve of the suggestion which the Committee has made of a required preliminary education for the student nurse and the recommendation of a study of such a plan

We commend the sympathetic and public spirited approach of the Committee to this difficult problem and recommend the continuation of the Committee for further study

I move the adoption of the Report
Motion seconded and carried

67 Physical Therapy

Dr Jennings Your Reference Committee approves the Report of the Committee on Physical Therapy, which deserves high commendation for the earnestness of its work (*Jour* May 1, p 561)

We wish to call attention to that part of the Report which discloses the existing degree of inertia among the County Societies

Twenty-nine societies have taken no action, 15 societies showed a retrogression from the activities of the preceding year, 6 societies remained about stationary Leaving only 10 societies of the entire State that have made progress in physical therapy

We are pleased to note that 57 per cent of the hospitals throughout the State possess physical therapy equipment, and 34 per cent of the remainder intend organizing such departments

We recommend the continuance of the Committee and

hope that another year will show greater interest and more progress in the County Societies.

I move the adoption of the Report.

Motion seconded and carried.

On motion duly seconded and carried the session thereupon adiourned until 8 P. M.

EVENING SESSION—8 P. M.

The meeting was called to order by the Speaker at eight P. M.

The Speaker: Is Reference Committee on New Business A ready to report?

68. Promotion of Medical Projects

Dr. Colie: The resolution proposed by Dr. Garen of Cattaraugus County (Sec. 30), Resolved, that it is the sentiment of the House of Delegates of the Medical Society of the State of New York that its members or committees shall not be permitted to engage in the promotion of the medical subject, state or national, requiring legislation, until such subject and the proposed legislation thereon shall have been submitted for consideration to the House of Delegates and approved by two-thirds vote.

I move that the recommendation be not approved.

Motion was seconded.

Dr. Leitner: That resolution was not offered by Cattaraugus County. It was offered by the delegate of Cattaraugus County without the endorsement of the County.

Motion that the recommendation be not approved seconded and carried.

69. Acceptance of Donations

Dr. Colie: By Dr. Garen of Cattaraugus (Sec. 30A): Resolved, that no member of this society or committee of this society shall be permitted to accept funds, grants, donations, or any form of financial assistance either directly or indirectly from personal or lay sources, for the promotion of medical projects requiring legislation, without permission from the House of Delegates given by two-thirds vote.

I move that the recommendation be not adopted.

Motion seconded.

Dr. Rooney: Mr. Speaker, this House five years ago adopted a resolution exactly the same in tenor as that which has been presented by Dr. Garen, and I proposed the resolution. So far as I know the House never rescinded its action. There was a very real reason for it then and I think there is a very real reason for it now.

I do not see why the Medical Society of the State of New York has to be the beneficiary of any fund or of any money outside of its own funds.

I hope the House of Delegates will not rescind that action which they took five years ago which was well based, and which I think is now well based.

I trust the recommendation of the committee will not pass and that the House will favor the adoption of the resolution.

The whole situation is briefly this: The original resolution stated that we should not accept money from other sources than our own funds.

The Reference Committee disapproves of this resolution.

If you vote for the committee's recommendation you will vote in favor of accepting money from other funds than your own. If you vote against it you will vote in favor of the resolution which we passed five years ago not to accept money from other sources than our own.

Dr. Colie: In view of the fact the chief criticism of this resolution is with the looseness of the wording rather than the severity of the principle I respectfully move it be re-referred.

Motion seconded and carried.

70. County Departments of Health

Dr. Colie: Resolution from Erie County (Sec. 22). That the House of Delegates declare itself opposed to any legislation to make compulsory the establishment of County Boards of Health, or County Health Units.

I move that the resolution be disapproved.

Dr. Bonnar: I object to the action of the Committee.

Dr. Rooney: I move that action upon this recommendation be postponed indefinitely.

Motion seconded and carried.

71. Optometry Law

Dr. Colie: Resolution from Erie County: That the secretary of the Medical Society of the State of New York obtain an opinion from the Legal Counsel for the society as to the constitutionality of the amendment to the Optometry Law enacted in 1931. (Sec. 23.)

It is recommended that this be adopted and I so move.

Motion seconded.

Dr. Bedell: I move that the opinion be printed in our Journal.

Seconded

Dr. Colie: I move that the resolution be adopted with the amendment.

Seconded and carried.

72. Sewage Disposal Plants

Dr. Colie: That the House of Delegates declare itself as opposed to any amendment to the law that shall centralize authority in the State Department of Health, concerning the location and erection of sewage disposal plants for municipalities. (Sec. 28.)

This resolution is not recommended on the ground it is ambiguous and not clear.

Dr. Thomson of Kings: Is it not true that the present state law authorizes or enables the State Health Department to interfere in sewage disposal and sanitation?

The Speaker: If there is anyone present who can answer that question I would be glad to hear from him. Dr. Rooney, can you answer Dr. Thomson's question?

Dr. Rooney: I can, if I may.

The present Public Health Law gives the State Department of Health the right to provide for the construction of or the prohibition of the construction of sewage disposal plants having affluents which may empty into a stream from which any of the other communities below that point draw their water supply. It gives them general police power over all the sewage disposal plants of the State of New York, and requires plans for all sewage disposal plants to be submitted to the State Department of Health prior to construction.

I do not believe any approval or disapproval will have any effect on this resolution. Therefore, I move that this resolution be postponed indefinitely.

Motion seconded and carried.

73. Minimum Wage for Physicians

Dr. Colie: Resolution introduced by Dr. Julius Ferber (Sec. 14): Whereas the Medical Society of the County of New York after considerable study of the exploitation of physicians by municipal and state department as well as by lay corporations, saw fit to endorse the movement, to demand the $5 minimum wage per hour for physicians employed on part time and,

Whereas because the economic distress now prevailing generally forces many physicians to accept the part time positions at lesser rate, therefore be it

Resolved, that the House of Delegates of the Medical Society of the State of New York records the opinion in favor of a minimum wage of $5 per hour, for physicians working upon a part-time basis, but be it further resolved that a $5 per hour minimum charge shall not be so construed as to constitute a demand for an increase

in salary in the case of medical men employed in regular positions under the Civil Service Laws nor for physicians holding regular departmental positions which after a term of service entitle the holder thereof to a pension

I move that this recommendation be not approved

Dr Rim of Kings I move that the resolution be tabled

Motion seconded and carried

74 MEDICAL PRACTICE BY CORPORATIONS

Dr Cohe Resolution introduced by Dr Julius Ferber (Sec 19) WHEREAS the Judicial Counsel of the Medical Association in its report as published in the American Association bulletin as of April 1931 regards the decision of Judge Samuel R Blake of the Superior Court of the State of California in and for the County of Los Angeles in the case of Granville McGowen plaintiff vs Medical Service Corp a corporation, defendant of being of the greatest importance at a time when commercial organizations established for profit are engaged in the sale of medical service in the matter that may be detrimental to the public good and opposed to the progress of the scientific medicine therefore be it

RESOLVED that the House of Delegates of the Medical Society of the State of New York instruct its counsel to bring suit against one of the medical agencies engaging as a corporation in the practice of medicine that this suit be pressed for a decision upon two fundamental questions

1 Can a corporation practice medicine?

2 Is the manner and method of the defendant corporation such as to constitute the practice and method recommended for adoption?

The Speaker It may be a departure from the usual order, but the Speaker wishes to ask a question What is the cost of such a thing going to be?

Dr Rooney I was just about to arise to ask the Speaker to request the Counsel of the Society to tell us just what a litigation of this sort means before it is terminated by a decision from the Court of Appeals in the State of New York It is a very expensive proposition and how it is going to affect us in the State of New York we cannot personally see So far as I know the Court of Appeals decisions in this state have uniformly held—and so far as I know still hold—a corporation can neither practice law nor medicine I should like to request the Speaker to ask Counsel whether I am wrong in that contention and whether a suit of that sort is not necessary

Mr Brosnan There is no question gentlemen under the decisions of the Court a corporation can neither practice medicine nor law I would hesitate to advise the adoption of this resolution since a proceeding of this kind would be extremely expensive for one thing and it may result in actions against this Society for another I think it is a situation we ought to go slow in I take it the resolution contemplates a criminal action against these corporations on the ground they are practicing medicine illegally It would mean the employment of investigators and the collection of evidence and the possibility of throwing the plaintiff which would be this society into some sort of libel action or action for malicious prosecution false arrest or something of that kind

I think it is a situation we ought to think over very carefully before any action is taken

I think this very resolution came before this body last year, but I believe it was withdrawn I do not think this lawsuit is necessary

Dr Ferber I fully appreciate the novelty as well as the magnitude of the undertaking advocated in this resolution but I also know that this is not a thunderstorm from a clear sky For the last four to five years medical men and women have discussed the advisability of initiating a test case in the courts of this state and to determine—first—whether corporations should be allowed to continue the practice of medicine under our Medical Practice Act, and—secondly—what constitutes medical practice by a corporation

Several years ago it was pointed out and rightly so that the Medical Society of the State of New York could not possibly start such action because it did not have the necessary funds to defray the expense incidental to such litigation Today we find that Providence has provided for this necessity through the agency of our capable Treasurer Dr Charles Gordon Heyd, during whose term of office the treasury of our State Society has managed to accumulate sufficient funds to enable it to protect the legitimate rights of the medical profession

There are those amongst us who claim that the bringing of such suit by our State Society is not practical because if we lose the Defendant Corporation would bring suit for damages amounting to many thousands of dollars Regardless of the merits of this objection I am at liberty to state that Providence has also provided for this emergency in the persons of self sacrificing physicians who are willing to act as Plaintiffs and bring suit against a corporation practicing medicine Unfortunately they have not the means to finance such action, but with encouragement from the profession they are ready to give their name, time and effort to the testing in the courts of the right of corporations to practice in this Empire State

As to the legal side of the question the decision rendered by the Superior Court of California in and for the County of Los Angeles in the case of Granville McGowen Plaintiff vs Medical Service Corporation, a corporation Defendant, sets ample precedent and gives us a real clue as to the sentiments of judiciary with regard to a corporation indulging in the practice of medicine The decision handed down by the eminent jurist Samuel R Blake contains in my opinion one of the most noble expressions of the ideal of medical practice that has ever been the privilege of any human being to utter He states The right to practice medicine attaches to the individual and dies with him and it can not be made a business sheltered under the cloak of corporations having marketable shares descendable under the law of inheritance ' In other words, the right to practice medicine is part and parcel of the individual not to be bartered commercialized or commissioned

We must consider, of course that the adoption of this resolution means action Unlike other resolutions which are merely an expression of opinion—kept on our minutes for future reference—the adoption of this resolution implies action responsibility and expense. But, who can point an accusing finger at our State Society that it ever lacked courage and initiative when the medical profession was in need of its influence and endeavor? We have been accused of being conservative but even our accusers admit that our conservatism has been tempered by deliberation We were never remiss in our duties to the medical profession but rather surveyed the field and studied the situation in order not to be carried away by the enthusiastic fancy of radicalism

Were we now to stand aloof and watch for developments outside of our sphere of activity and influence to bring about the occasion of corporate medicine we may be adjudged simpletons not knowing how to protect a rare privilege Nay! We may even be adjudged as indifferent to the degrading influence of corporate medicine on medicinal practice

I am confident that each and every one of you assembled here today fully evaluates the significance of this resolution and that you will vote for its adoption

Dr Wightman We have here tonight a man from the Department of Education Dr Rypins whom I think will speak very briefly and illustrate this thing for us

He is not a member of this Assembly but if it is the pleasure of this House to hear from him for two or three minutes, I think he will favor us with his remarks

The Speaker: Is there any objection on the part of the House of Delegates to hearing Dr. Rypins?

The House granted Dr. Rypins the privilege of the floor.

Dr. Rypins: I think Dr. Rooney has expressed the situation as well as I can. The question as to whether or not a corporation can practice medicine in New York State has been decided on numerous occasions, and within the last three or four years the Attorney General, with the cooperation of the Department of Education, has dissolved several corporations who had been guilty of practicing medicine without licenses.

I do not know what particular corporations you are talking about, but if there is any one who has a particular corporation in mind, the procedure is to refer the matter to me with the facts, and we will attempt to find out whether or not there is a violation of law.

It is not necessary to get a decision of the Court of Appeals. The Court of Appeals has already ruled on that in this state.

You must bear in mind, however, that there are corporations chartered under the Public Welfare Law, such as charitable clinics, and although they are incorporated, they are not incorporated for profit and they cannot be stopped under our law from practicing medicine.

I think most of the complaints you have in mind will have to be brought before the Department of Public Welfare. If, however, you have in mind other corporations for profit which are in your opinion practicing medicine, the proper procedure is to refer all the facts to me with a request for an investigation and prosecution, if the the facts warrant it.

Dr. Rooney: I move that the resolution lie on the table.

Motion seconded and carried.

75. Volstead Act

Dr. Colie: Presented by New York and Warren Counties (Sec. 9).

Whereas, Congress has undertaken to fix the dose of wine, whiskey and brandy by legislative fiat, thus taking over the functions of Pharmacologists and physicians, and

Whereas, the Volstead Act compels physicians to betray the confidences of their patients by keeping a record of their diseases and ailments which records are open for inspection by Federal Prohibition agents, thus violating the traditions of the medical professions, medical ethics and the laws of a number of our states, and

Whereas, relief from these conditions has been sought in the courts and has been denied by the United States Supreme Court, and

Whereas, the Wickersham commission has unanimously made the recommendation; "Removal of the causes and irritation and resentment on the part of the medical profession by: (a) doing away with the statutory fixing of the amount which may be prescribed and the number of prescriptions. (b) Abolishing of the requirements of specifying the ailment for which liquor is prescribed in the book which becomes later a record in the files of the Revenue Department. (c) Leaving as much as is possible to regulation rather than by fixing details by statute."

Now Therefore Be It Resolved, that the Medical Society of the State of New York hereby formally expresses its disapproval of those portions of the Volstead Act which invade the right of the State of New York to regulate the practice of medicine within its own borders and which deprive the physician of his right to do the free exercise of his judgment in the practice of his profession, and

Be It Further Resolved, that the Medical Society of the State of New York demand of Congress the repeal of the said portion of the Volstead Act, and

Be It Further Resolved, that the Medical Society of the State of New York urge each of its members to demand of his Senators and Congressmen the repeal of the said portions of the Volstead Act, and

Be It Further Resolved, that the Secretary of the Medical Society of the State of New York be and hereby is instructed to transmit a copy of these resolutions to the Senators from New York and to each representative of the State of New York in the House of Representatives, and

Be It Further Resolved, that the delegates of the Medical Society of the State of New York to the House of Delegates of the American Medical Association be and hereby are instructed to present a similar resolution to the House of Delegates of the American Medical Society for action at the next meeting.

I move the adoption of this resolution.

Motion seconded and carried.

76. Report of Secretary

Dr. Krieger: The Reference Committee to which was referred the reports of the Secretary, Council, Councillors, and the Board of Censors, would respectfully offer the following:

We are deeply conscious of the increasing duties that confront the Secretary of a Society of such magnitude as ours has become, and appreciate the necessity of having for that office one who has the pulse of the profession constantly under touch, one who is familiar with the various reactions that arise in the rapid changes which are taking place in society, pertinent to the physician, one whose wisdom in the handling of problems that arise all over the State, is sufficient to keep everyone happy and satisfied, one whose wise counsel and judgment are sought after and heeded by the members of our profession. Such a person we have in our Secretary, Dr. Daniel S. Dougherty. The Committee at this time wishes to extend to him their sincere appreciation of the results of his untiring efforts in behalf of our Society, and to express to the Society its congratulations in having for the office of Secretary, one who has shown the ability, courage and sincerity that Dr. Dougherty possesses. (Jour., May 1, p. 524.)

77. The Office Organization

Your Committee commends that portion of the report which deals with the Society in general, and feels that the references to those who are in charge of the offices in New York City and Albany are deserving and timely, and recommends the adoption of that portion of the report as representing the sentiments of the Society. (Jour., May 1, p. 524.)

I move the adoption of this recommendation number one.

Motion seconded and carried.

78. Financial Department

Dr. Krieger: Your Committee concurs in that portion of the report dealing with the financial department, (Jour., May 1, p. 525) and feels that, with the method used in handling the finances of the Society, the high qualities of the Trustees and Treasurer, and the excellent condition of the Treasury, that the interests of the Society are certainly thoroughly safeguarded.

I move the adoption of this portion of the report.

Motion seconded and carried.

79. Legal Department

Dr. Krieger: The commendation of the Secretary regarding the Legal Department is carefully noted and approved, (Jour., May 1, p. 525) and the Committee recommends that the House of Delegates extends its thanks to the Counsel of the Society, Mr. Lorenz J. Brosnan, and his associates, for their results in the handling of the legal problems which confront the Society and its individual members.

I move the adoption of this portion of the report.

Motion seconded and carried.

80. COMMITTEES

Dr. Kreiger: The excellent work done by the standing and special committees as mentioned in the Secretary's report (*Jour.*, May 1, p. 525) is worthy of approval by the Society and a vote of appreciation to them is hereby recommended.

I move the adoption of this recommendation.

Motion seconded and carried.

81. COMMITTEE ON REVISION OF BY-LAWS

Dr. Krieger: The Committee approves the portion of the report, that a revision of the Constitution and By-Laws are needed in view of changing conditions, and the suggestion of the Secretary as to the personnel of a committee to make such revision has been given serious consideration, (Jour., May 1, p. 525) and it therefore recommends that the House of Delegates approve the suggestion, namely, that the President-Elect, the Secretary and Speaker, together with Drs. Ludlum of Kings, Rooney of Albany, Farmer of Onondaga, and Trick of Erie, be appointed such Committee to report at the next annual meeting in 1932.

I move the adoption of this recommendation.

The Secretary: In regard to that recommendation, I would like to make an explanation. There is somewhat of an error. When I wrote that I meant the House recommend for the President for appointment, not that the House appoint. I have told Dr. Johnson that, because it is Dr. Johnson's prerogative to appoint the committee.

The recommendation was seconded and carried. (See also Section 115.)

82. DISTRICT BRANCHES

Dr. Krieger: It is interesting to the Committee that the report of the Secretary shows an increased interest in the District Branch meetings as evidenced by the attendance (Journal, May 1, Page 526), and it is recommended that these meetings be given all the publicity possible in order to bring together even greater numbers of the members for their mutual benefit.

I move the adoption of this recommendation.

Motion seconded and carried.

83. STATE-WIDE CONFERENCES

Dr. Krieger: The Conference of County Secretaries, Legislative Chairmen, and Public Relation Chairman (Journal, May 1, Page 526) have been productive of excellent results, and the recommendation of the Secretary that they be made an annual feature is hereby approved.

I move the adoption of this recommendation.

Motion seconded and carried.

84. INSURANCE COMMITTEE

Dr. Krieger: The Committee feels in accord with the Secretary's attitude that the work of the Insurance Committee (Journal, May 1, Page 526) has been effective, and approves the recommendation that the Chairman be authorized to visit and address the District Branch Meetings. (Section 89.)

I move the adoption of this recommendation.

Motion seconded and carried.

85. DR. E. ELIOT HARRIS, IN MEMORIAM

Dr. Krieger: The death of Dr. E. Eliot Harris (Journal, May 1, Page 527) has removed from our midst a great man, one whose interests in the welfare of this Society were manifold, and who as Speaker of this House presided over its deliberations with fairness in every respect.

The recommendation of the Secretary, that this House, by formal action, pay fitting tribute to the memory of Dr. Harris is heartily endorsed, and recommends that a Committee be appointed by the President to prepare suitable resolutions to be spread on the minutes.

I move the adoption of this recommendation.

Motion seconded and carried.

86. MEMBERSHIP

Dr. Krieger: The Committee notes with considerable gratification that the membership in the State Society has shown a substantial gain during the past year (Journal, May 1, Page 527), and it is recommended that an attempt be made to induce each man qualified to take membership in this Society.

I move the adoption of this recommendation.

Motion seconded and carried.

Dr. Krieger: I move the adoption of the report of the Reference Committee as a whole.

Motion seconded and carried.

87. BUFFALO FOR NEXT ANNUAL MEETING

Dr. Bonnar of Erie: Not having been heard very much this afternoon I wish to speak to this House of Delegates on a very important matter while you are still in your right minds.

I do not know whether I have the privilege, but I wish to say the object of my rising is to extend an invitation. Have I the floor?

The Speaker: I am going to allow you the floor.

Dr. Bonnar of Erie: The Erie County Medical Society has placed upon myself and the delegation from that County the great responsibility and the great pleasure of extending an invitation to the Medical Society of the State of New York to hold its meeting in 1932 in Buffalo, which will be the centennial of our existence as a city.

The Secretary: I move we accept the invitation.

Motion seconded and carried.

87. REPORT OF COUNCIL

Dr. Krieger: The Committee after carefully reading the report of the Council (Journal, May 1, Page 527), which includes the work done by the Executive Committee, feels that the Society is to be congratulated on having a group of men who have given so much of their time and attention, as the report shows, to the various matters which concern the Society, all of which has been done without remuneration or expectation of reward. The accomplishments during the year are worthy of the support of this House, and a vote of confidence is hereby recommended.

I move the adoption of this recommendation.

Motion seconded and carried.

88. PUBLICATION COMMITTEE

Dr. Krieger: The Committee feels that it should at this time commend the Publication Committee, the Editor in Chief, and the Executive Editor (Journal, May 1, Page 529) for the large amount of work they have done in improving the Journal, and they recommend that every member be urged to read his Journal more thoroughly, that he may be better acquainted with the doings of our Society.

I move the adoption of this recommendation.

Motion seconded and carried.

89. INSURANCE COMMITTEE

Dr. Krieger: It is gratifying to the Committee that the cost of malpractice insurance under our group plan has been revised, and that the revision is downward. (Journal May 1, Page 529.)

The Insurance Committee has prepared a set of resolutions regarding the question of malpractice coverage, which are printed in the report of the Council, and after having carefully studied them your Committee approves and recommends their adoption. (Section 84.)

I move the adoption of this recommendation.

Motion seconded and carried.

90. Principles of Professional Conduct

Dr. Krieger: The Committee to revise the Principles of Professional Conduct (Journal, May 1, Page 530) has made several suggestions and presents in the report of the Council a Revision of the entire matter. It is the opinion of the Reference Committee that this amended code is proper and pertinent and it recommends the adoption of the revision as suggested.

I move the adoption of the principles of Professional Conduct as revised.

Motion seconded and carried.

Dr. Krieger: I move the adoption of the report of the Reference Committee as a whole.

Motion seconded and carried.

91. Board of Censors

Dr. Krieger: The Reference Committee on the report of the Board of Censors (Journal, May 1, Page 533) finds that there was but one meeting held during the year, and at the end of the hearing on the appeal presented to it, by mutual agreement, the appeal was withdrawn.

I move the adoption of the Report of the Board of Censors as published.

Motion seconded and carried.

92. Report of Councillors

Dr. Krieger: The Reference Committee on the reports of the Councillors (Journal, May 1, Page 570, and May 15, Page 651), after carefully reading the reports, finds that the annual meetings of the various District Branches were well attended, and that the programs were exceptionally interesting and instructive, all of which reflects the interest and cooperation on the part of the Presidents of the various branches.

The Committee notes that the officers of the State Society were in attendance at most of these meetings and participated in the deliberations.

It is gratifying to note that the attendance at these meetings have been steadily increasing, indicating that they should be continued and encouraged.

We commend the various Councillors for their work in making these meetings a success.

I move the adoption of this Report.

Motion seconded and carried.

Dr. Krieger: I move the adoption of the report as a whole.

Motion seconded and carried.

93. Committee on Arrangements

Dr. Smiley: Your Reference Committee begs leave to report as follows:

The Report of the Committee on Arrangements (Journal, May 1, Page 549) speaks for itself. We commend the diligence and fidelity with which the general plan and the many details for the meeting have been anticipated and perfected for the benefit and pleasure of the members of the Society.

We commend the appreciation and thanks of this Society to the Committee for their labors.

I move the adoption of the report.

Motion seconded and carried.

94. Committee on Scientific Work

Dr. Smiley: Your Reference Committee on the Report of the Committee on Scientific Work (Journal, May 1, Page 557) has carefully studied this report and commends the committee for the excellent scientific program it has arranged for the benefit of the Society.

Your Reference Committee begs leave to quote the following paragraph from the report of this Committee:

"Your Committee has had great difficulty in arranging an instructive program because of the conflict between our meeting and that of many of the special societies. We most respectfully suggest that, if possible, our annual meeting be held at a time when the leaders of medical thought are not obligated to attend their special societies."

Your Reference Committee recognizes the importance and seriousness of the situation referred to and recommends to the officers of the State Society charged with the designation of the date for State Society meetings the desirability of conferences with officers of the Special Scientific Societies concerned, with the view of removing conflicting meeting dates as far as possible to the mutual advantage of all the members of all the Societies concerned.

We recommend the appreciation and thanks of the Society to this Committee for the efforts of their labors.

I move the adoption of the Report.

Motion seconded and carried.

95. Periodic Health Examinations

Dr. Cunniffe of the Bronx: This is the first yearly report of the five-year program of the Committee. (Journal, May 1, Page 558.) The activities during the past year were concerned primarily with the formulation of a policy and a procedure to bring about the health examinations of all of the citizens of the State of New York, and that such examinations should be conducted primarily in the offices of private physicians. The scheme of the Committee involves, first, the bringing of the public to the physician's office and, second, a good and satisfactory health examination.

Their program consists in aiding the physician in giving addresses on health examinations to lay audiences and a series of suggestions have been prepared by the Committee, and will be shortly published. Also the program for the next year is concerned with the health examination of women, and a selective list of topics for a series of medical articles and addresses, on the health examination of women, is published in this report. This is a very excellent idea and the Committee highly approves of it.

I move the adoption of this portion of the report.

Motion seconded and carried.

96. Post-Graduate Education in Health Examination

Dr. Cunniffe: Post-Graduate medical education in the matter of efficient and satisfactory health examinations (Journal, May 1, Page 559) has been considered, and a series of lectures and clinics has been given to the Queens County Medical Society and the Tioga County Medical Society.

The Committee feels that this supplementary education in health examinations by the private physician is very necessary, if we are ever to succeed in bringing the public to the physician's office. Consequently, we approve this line of endeavor and urge that it be offered to the other County Societies of the State.

I move the adoption of this portion of the report.

Motion seconded and carried.

97. Questionnaire—Health Examinations

Dr. Cunniffe: The remainder of the Report discusses the matter of a questionnaire for the securing of information regarding health examinations (Journal, May 1, Page 559) and also the many avenues through which this matter can be brought to the public. Special notice taken of the offer of a radio outlet giving a thirty to fifty station hookup every week for fifteen minutes between ten and eleven o'clock in the morning for the coming year. This time is best for reaching the women in the home, and coordinates with the present effort to advance the health examination for women as the major project for this year and next. It is proposed to provide a medical speaker, who will submit his talk to the Committee two months in advance, to be edited and brought into harmony with the standards of the community. The

Committee proposes to cover the field of women's health examinations in a substantial, practical and inspiring fashion, with special reference to the service of the practicing physician in this oncoming field of preventive medicine.

I move the adoption of this part of the report
Motion seconded and carried

Dr Cunniffe I move the adoption of the report as a whole
Motion seconded and carried

98 COMMITTEE ON MEDICAL RESEARCH

Dr Cunniffe This Report discusses the opposition to the anti vivesection bill both in the State Legislature and in the Federal Congress (Journal, May 1, Page 557) The Report states that the Bill was committed to the Committee on Codes of the State Legislature and no further action could be reported at that time We note with pleasure the personal appearance in opposition to these bills of the representatives of many of the institutions concerned with medical education However, the effort against the bill in the Federal Congress was limited to letters of correspondence to our Congressmen and Senators We feel that this bill, which must be fought every year, is of too great importance to be allowed to pass without personal appearance at the hearings in opposition to the bill Consequently, we urge that the Chairman of this Committee for the next year be urged to provide personal representation at all hearings in opposition to these measures

I move the adoption of this report
Motion seconded and carried

99 RETIREMENT FUND FOR PHYSICIANS

Dr Kalish Your Reference Committee on New Business C has a resolution introduced by Dr William Patterson of New York County as follows (Section 12)

WHEREAS, No provision at present exists in the Medical Society of the State of New York for retirement stipends for physicians in the State of New York, and

WHEREAS in certain other professions such provision has been successfully made, and

WHEREAS, it would seem advisable that the delegates here assembled should take appropriate action to this end,

BE IT THEREFORE RESOLVED that the Medical Society of the State of New York through its delegates here assembled appoint a Committee of not fewer than five to study ways and means of establishing a Retirement Fund for the benefit of the members of the Medical Society of the State of New York, and

BE IT FURTHER RESOLVED that said Committee be prepared to make a Report at the next regular meeting of this body

I move the adoption of this resolution
Seconded and carried

100 RECOGNITION OF AMERICAN PHYSICIANS IN FOREIGN COUNTRIES

Dr Kalish We have two resolutions similar in nature introduced by the County of New York as follows

WHEREAS, many foreign countries do not recognize graduates of American Medical Schools, nor permit them to practice medicine,

THEREFORE BE IT RESOLVED by the House of Delegates of the Medical Society of the State of New York, that this situation be brought to the attention of the Regents of the State of New York for the purpose and to the end that some degree of reciprocity be established and that the existing discrimination against American doctors be stopped (Section 17)

WHEREAS many foreign countries do not recognize medical diplomas granted in the United States and do not permit American doctors, graduates of American Medical Colleges, to practice, and

THEREFORE BE IT RESOLVED that the House of Delegates of the Medical Society of the State of New York instruct its delegates to the American Medical Association to bring this situation to the attention of the House of Delegates of the American Medical Association for the purpose and to the end that this unjustified disqualification of graduates of medical schools of the United States be discontinued and that American physicians desiring to practice in foreign countries be granted the same rights and privileges as their nationals have in the United States (Section 15)

Committee on New Business C approves both resolutions pertaining to the rights of American graduates to practice in foreign countries and to bring this situation to the attention of the Board of Regents of the State of New York to the end that reciprocity be established for practitioners duly licensed to practice in the State of New York

I move the adoption of these resolutions
Motion seconded and carried

101 BIRTH CONTROL

In regard to the resolution adopted by Erie County on May 18 1931 (Section 24), that the House of Delegates of the State Society declare its opposition to the introduction or enactment of any legislation that shall change the policy in the matter of Birth Control, your Reference Committee recommends that since the State Society has taken a stand along these lines that no further action should be taken by the House of Delegates at this time

I move the adoption of the recommendation
Motion seconded and carried

102 PAY CLINICS

Dr Kalish Resolution introduced by Dr Subkis of New York (Section 18)

WHEREAS, there is an increasing tendency on the part of dispensaries and the Out Patient Departments of Hospitals and Medical Centers to conduct Pay Clinics and

WHEREAS, these Clinics diagnose and treat patients *outside of the Provision of the New York State Dispensary Law,*

THEREFORE BE IT RESOLVED that the Committee on Legislation initiate legislation at the next session of the New York State Legislature to the effect of preventing Pay Clinics from being operated under dispensary laws

Your committee approves this resolution and is of the opinion that the operation of pay clinics under the guise and with the aid of philanthropic agencies is to be deprecated under present laws Special and new laws are necessary to meet this *new situation which has arisen* through the establishment of pay clinics

I move the adoption of the recommendation
Motion seconded and carried

103 CULTISTS' LEGISLATIVE BILLS

Dr Kalish We have a resolution introduced by Erie County

RESOLVED, that the Medical Society of the County of Erie pledges its whole hearted support to assist the State *Committee on Legislation* in defeating cultists' bills by personal interviews with legislators from Erie County prior to the next election (Section 27)

Your committee finds that it is rather difficult to understand why this resolution was introduced Your committee finds no action is necessary by the House of Delegates

I move the adoption of the report
Motion seconded and carried

104 LEGAL COUNSEL

Dr Dyo The Reference Committee on the report of the legal counsel (Journal, May 1, Page 536) begs to submit the following

Mr. Brosnan has completed his first year's work in the new position of Legal Counsel with marked success. This success we believe is due to the fact that he has continued the policy which he helped to inaugurate eleven years ago. Namely, that of creating a better understanding between the profession and the lay public.

The editorial work in number and subjects treated equal those of previous years.

The case reports exceeded those of the previous year by four.

The reduction in the number of personal inquiries have been reduced by ten. This reduction the committee interprets is because more of the members of the State Society are reading the editorials and case records, thus becoming more familiar with the legal aspect of their practice.

This year Mr. Brosnan announces that a book on The Legal Relations Between the Physician and the Patient by Mr. Stryker and himself will be completed.

This is the first up to date book on this subject published since 1911 by Wilson.

The committee wish to take this opportunity to thank the authors for their contribution to medical literature along the lines of their established policies of helping the public to better understand some of the physician's economic and professional problems.

The litigation work of our counsel has been as heavy as usual. There was an increase in the number of suits this year from 192 of the previous year to 286 this year.

Cases disposed of were 159 as against 144 or an increase of 15 cases for the year. Of this 159 cases 26 were settled, 130 dismissed or discontinued. Only 3 cases resulted in a judgment for the plaintiff and 1 of these 3 cases is now on appeal.

The cases now in court show an increase of 127 over the number of cases for last year at this time.

The report of the members availing themselves of the group insurance is very encouraging. There has been a gain of 32% of the 498 new members taken into the Society this year over last year which is far better than the previous year. This reflects the untiring efforts of Drs. Card and Heyd, the Society's Insurance Committee.

The Committee wishes again this year to encourage each County Society through its delegates to do its bit and continue this steady gain in members of the State Society taking out a group malpractice insurance, in order that our Legal Counsel may feel he has a united front of the profession behind him to continue his policies for a better understanding of the problems of the Medical Profession.

This Committee feels that in Mr. Brosnan the Society has an untiring, conscientious, and excellent counsel. The Society should feel as judged by this committee that its legal affairs would not be better cared for than by its present incumbent.

I move the adoption of this report.

Motion seconded and carried.

105. Public Health and Medical Education

Dr. Howland: The Reference Committee on the Report of the Committee on Public Health and Medical Education has carefully reviewed the reports of the Committee. (Journal. May 1, Page 541.)

We commend the policy of the Committee, which in brief consists of two parts: *First:* Investigation of Public Health activities and the education of the physician in such matters. *Second:* "A contribution in the field of public health on the part of the medical profession, in aiding to provide adequate medical care through the continued instruction of the physician by means of graduate education."

The tabulated figures in the report of the Committee show that only one-third of the component county societies have availed themselves of these courses. There should be more. The figures indicate that the cost of the work has been gradually reduced. We commend the recommendation of the Committee that small adjacent county societies join in these courses. We urge the component County Societies to be particular to appoint a strong committee on graduate education and that these committees consult with the State Committee and be guided in a large measure by its suggestions as to courses and time for the lectures.

We commend the Committee's proposal to make available courses on Tuberculosis and Obstetrics and Pediatrics, which subjects have not been presented in the last three years. We are heartily in accord with the Committee's plan of maintaining an active interest in general public health activities, and in endeavoring to stimulate county societies to appoint active committees on this subject. The need for such committees is specially urgent at the present time, in view of the new health legislation recently enacted in this State.

We concur in the Committee's view that it is regrettable to have to admit that the Committee on Public Health of the State Society, as well as County Societies, has not been consulted about these matters during the period of investigation and during the construction of legislative bills.

We desire to express our appreciation of the great amount of work which the Chairman and Committee has accomplished during the past year, and well within the appropriation made to the Committee.

Knowing something of the prospective plans for the coming year, we wish to recommend that there be no change in the Chairmanship of the Committee, that the work of the Committee may go progressively on.

I move the adoption of the report.

Motion seconded and carried.

106. Cancer Prevention

Dr. Howland: The Reference Committee on the Report of the Committee on Cancer Prevention (Journal, May 1, Page 544) heartily endorses the report as printed, and we urge that the County Societies do devote, as the Committee recommends, one meeting a year on the subject of cancer and that the Committee consult with the State Committee in obtaining able speakers for such meetings.

We congratulate the Chairman in making such progress in the education of the physicians and the public.

I move the adoption of the report.

Motion seconded and carried.

107. Board of Trustees

Dr. Sobel: The Reference Committee's report on the report of the Board of Trustees. (Journal, May 1, Page 532.)

This Committee commends the report of the Board of Trustees on its management of the finances of the Society, and its handling of the Society's investments.

In these times of depreciation, too much care cannot be exercised in the selection of securities which meet the requirements of Trust Funds, and it is the opinion of this committee that the Board of Trustees have used all possible precautions as represented by their consultations with the different groups of experts, namely:

1. Financial Expert; 2. Banking House; 3. Brokerage Firm.

In the creation of three distinct trust funds the Board of Trustees have displayed excellent judgment for the future safeguarding of the Society's Financial welfare, as enumerated in this report.

1. Journal Fund; 2. Directory Fund; 3. The General Investment Fund.

The dovetailing of the Budget System of the three departments, namely, Executive Committee, Board of Trustees, and Treasurer, form an absolute check on our expenditures for the current year.

I move the adoption of the report.

Motion seconded and carried.

108 Report of the Treasurer

Dr Sobel Your Reference Committee on the Report of the Treasurer begs to submit the following (Journal, May 1, Page 534)

The Treasurer is to be highly complimented on his report of the finances of the society His reports show that the society is on a sound financial basis, and too much credit cannot be given to him for his tireless and unceasing efforts to effect the same

A thorough examination of the Treasurer's statement for 1930-1931 indicates that he has had a surplus of almost $16 000, which he and the Board of Trustees have invested most judiciously This item alone represents a sum of over $1 25 per member of the society, which is building up a surplus and which should be encouraged for the good of the society from a financial standpoint

Your Rerefence Committee wishes to comment upon the low cost of operating the business side of the society, which represents total disbursements for the years 1930 1931 of $158 896 57 and income of $178 660 75, making a net profit of $16 044 59, giving its members in return an excellent medical journal, an annual directory, post graduate courses, legal protection of the best quality, annual meeting, considerable protection against vicious legislation and other items too numerous to mention

We heartily commend the treasurer's policy of his budget methods and building up a sinking fund for the good and welfare of our organization

I move the adoption of the report

Motion seconded and carried

109 Public Relations Committee

Dr Cottis The Report of the Committee on Public Relations (Journal May 1, Page 545) stresses the necessity of medical men cooperating with all health agencies whether lay or governmental and their pushing forward to a greater extent than formerly the newer ideas in medicine relating to health measures and the prevention of disease We endorse this portion of the report and move its adoption with the understanding that the State Medical Society retain its leadership in public health matters

We endorse this section of the report and move its adoption

Motion seconded and carried

110 Principles for County Committees on Public Relations

Dr Cottis The Committee recommends the following principles to County Committees on Public Relations (Journal, May 1, Page 546)

1 The activities of each County Committee should consist in expanding the health work which is already being undertaken in the county by any organization as well as to initiate new measures

2 The members of each County Committee shall seek to establish intimate contacts with the leaders of every volunteer health organization in the county They shall not wait for invitations to cooperate with the lay organizations, but shall take the initiative if necessary, in proposing it

3 The Committee shall offer the advice and assistance of the medical profession as to the most practical ways of conducting any form of health service in the county, and if possible shall see that every health organization in the county shall include at least one local physician on its governing body

4 The State Committee on Public Relations is in the position to give consultation and advice to any county committee in caring for its problems in the field of Public Relations

We endorse this portion of the report and move its adoption

Motion seconded and carried

111 Conferences County Chairmen

Dr Cottis The committee emphasizes the importance and value of the conference of chairmen of County Public Relations Committees Journal May 1, Page 545), and feels that it justified the expenditure of money It recommends that the conference be continued every year We endorse this section of the report and move its adoption

Motion seconded and carried

112 County Hospitals Rules for

Dr Cottis The Committee has considered rules and regulations to govern county hospitals that are to receive State aid The following are the recommendations (Journal, May 1, Page 546)

1 All registered physicians residing in the county shall be eligible to membership on the staff Physicians residing outside of the county may use the hospital but cannot become voting members of the staff

2 From their number they shall nominate for election by the board of managers a medical board of not less than five members

3 The medical board subject to the approval of the board of managers and the State Commissioner of Health, shall have supervision and control of all medical service in the hospital This shall include appointments for the necessary, efficient and adequate surgical, medical, special and nursing services of the hospital the preparation of rules and regulations for the conduct of the professional work of the hospital and the formulation or whatever by laws seem necessary for the efficient conduct of its (medical board's) business

As indicated by this resolution, the committee was unanimous in feeling that every provision should be made to guarantee the privileges of these county hospitals to every practicing physician in the county

We endorse this portion of the report and move its adoption

Motion seconded and carried

113 Welfare Law, and Crippled Children

Dr Cottis In regard to the separation of the law relating to the medical care of the physically handicapped child and the public welfare law, the Committee on Public Relations offers the following conclusions (Journal May 1, Page 547)

1 That the intent of the laws is to have the State assist those who because of some physical or mental infirmity are not able to exercise their full privileges of citizenship to remedy or remove such infirmity,

2 That the State prefers to have such medical care rendered in the homes when practicable and possible rather than in State or County provided institutions Hospitalization for such surgical care is expected and for such purpose the local hospital is to be preferred,

3 That the immediate responsibility for the supervision and conduct of all such work should rest with the proper local body or official,

4 That the welfare officer when possible should employ the physician preferred by the indigent,

5 That the State Department of Health which is authorized to make examination of physically handicapped children should do so for the purpose of approving or disapproving the recommendations for medical treatment made by the court but should not express a preference for attending physician or surgeon nor refuse to honor bills submitted for work performed if charges are commensurate with those generally prevailing in that community

6 That the State should use its offer of assistance to encourage communities to take financial responsibility of the care of its wards and not to stress clinic work

where physicians and hospitals receive no compensation.

7. Every county society should, by resolution, present formal communications to the judge of the children's court and welfare officials offering the services of the members of the Society.

We endorse this portion of the report and move its adoption.

Motion seconded and carried.

114. Future Plans

Dr. Cottis: The Committee has outlined as a program for future work (Journal, May 1, Page 548) that it will seek a conference with representatives of Federation of Labor for the purpose of discussing the function of the physician in the administration of the Workmen's Compensation Law. It also proposes similar conferences with the Parent-Teachers' Association, the Farm Bureau and Home Bureau, Chambers of Commerce, the Women's Clubs of the State and the Conference of Mayors, for the purpose of developing a closer relationship with these various organizations and to bring to them the attitude of the medical profession toward the various health problems with which they may be concerned. We endorse this section of the report and move its adoption.

Motion seconded and carried.

Dr. Cottis: In view of the great amount of conscientious and painstaking work performed by this Committee under the Chairmanship of Dr. Sadlier, we highly commend its efforts and move a vote of thanks to the committee.

Dr. Cottis: I move the adoption of the report as a whole.

Motion seconded and carried.

The Speaker: Members of the House of Delegates, is there anything else to come before this House?

115. Revision of By-Laws

The Secretary: The following amendments to the Constitution and By-Laws adopted at the last Annual Meeting held in Rochester were referred to this Meeting for action.

By-Laws:

Chapter X, Section 10. *Amend to read:*

"At least one month before the meeting of the House of Delegates the Speaker shall appoint such Reference Committees as he shall deem expedient for the purposes of the Meeting. Immediately after the organization of the House of Delegates he shall formally announce the appointments to the committees. Only members of the House of Delegates are eligible for appointment on the Reference Committees. Such committees shall consist of five members, three members constituting a quorum, and shall serve during the meeting at which they are appointed."

Chapter X, Section 11. *Amend to read:*

"Reports of Officers and Standing Committees shall be printed at least one month before the meeting of the House of Delegates and sent to the members of the Reference Committee appointed according to Section 10 for their preliminary consideration. All recommendations, resolutions, measures and propositions presented to the House of Delegates and which have been duly seconded shall be referred immediately to the appropriate reference committee."

Chapter IX, Section 3. *Add:*

"The appellant must also state if he desires to be present in person or by counsel. In the event that the appellant shall so declare, he must file with the notice of appeal a bond in the sum of Five Hundred Dollars to cover the costs of said appeal. In the event that the appellant fails to appear, either in person or by counsel, after making the aforesaid declarations, he shall forfeit to the State Society such share of said bond as represents necessary expenditures incident to convene the Board of Censors on said appeal."

Chapter IX, Section 7. *Add:*

"The Appellant must also state if he desires to be present in person or by counsel."

Chapter II.

Omit "(d) Trustees" and substitute the letter (d) for (e).

Chapter III, Section 1.

Omit "Trustees" in first line and "Trustee" in second line from bottom.

Chapter II, Section 2.

Omit "Trustees" in third line.

I move that they be referred to the new Committee to Revise the Constitution and By-Laws.

Seconded and carried. (See also Sec. 81.)

116. Retired Memberships

The Secretary: The following gentlemen have been recommended by their County Societies, the recommendation being signed by the Secretary and President of each County Society for retired membership.

Felix Cohn, New York City; D. Bryson Delevan, New York City; Albert Warren Ferris, East Orange, New Jersey; George Henry Fox, New York City; Eli H. Long, Buffalo; John Middleton, Buffalo; George E. Munroe, New York City; Russel C. Paris, Hudson Falls; Willis H. Proctor, Peekskill; E. Benjamin Ramsdell, White Plains; William G. Telfair, Astoria; John B. Todd, Syracuse; Franz J. A. Torek, New York City; Frank T. Hopkins, New York City; Charles W. Geel, Berlin.

I move they be elected to retired membership.

Motion seconded and carried.

117. Remuneration of Dispensary Physicians

Dr. Sadlier: Whereas, at a meeting of the Coordinating Committee of the Five County Society of the City of New York, a resolution was offered and passed, that it was the opinion of this Committee that physicians working in dispensaries should receive remuneration, and

Whereas, this resolution was ordered referred to the Five County Societies for their consideration and action, and also to the Medical Society of the State of New York for consideration and action,

Be It Resolved, that it is the sense of the House of Delegates of the Medical Society of the State of New York that Dispensary Physicians should receive remuneration for their services.

The Speaker: Referred to Committee on New Business A (Sec. 121).

Dr. Bedell moved that the Assembly adjourn until 9 A. M. Tuesday morning, June 2, 1931. Seconded and carried.

(The House thereupon adjourned.)

Adjourned Session of the House of Delegates
Tuesday, June 2, 1931

The meeting was called to order by the Speaker at 9 A. M.

118. Roll Call

The Speaker: The Secretary will please call the roll.

The Secretary called the roll and the following delegates responded:

Frederic C. Conway, William P. Howard, Brayton E. Kinne, Lyman C. Lewis, Irving Smiley, Isidore J. Landsman, Edward R. Cunniffe, Cornelius J. Egan, Louis A. Friedman, Vincent S. Hayward, Jacob A. Keller, Edward C. Podvin, Frank M. Dyer, Arthur S. Chittenden, Joseph P. Garen, Louis F. O'Neill, Edgar Bieber, George W. Cottis, Reeve B. Howland, Earl W. Wilcox, Anton S. Schneider, Charles J. Kelley, Robert

Brittain, C. Knight Deyo, William A. Krieger, Aaron Sobel, John D. Bonnar, James H. Donnelly, Albert A. Gartner, Mary J. Kazmierczak, Charles Leone, Edward J. Lyons, Francis M. O'Gorman, Milton G. Potter, Charles C. Trembley, Sylvester C. Clemans, Milton P. Messinger, Howard C. Murray, Joseph D. Olin, Robert F. Barber, Elias H. Bartley, John L. Bauer, Siegfried Block, George I. Swetlow, E. Jefferson Browder, William Linder, Frederic E. Elliott, Edwin A. Griffin, Alec N. Thomson, John E. Jennings, Simon Frucht, Walter D. Ludlum, Joseph W. Malone, Charles T. Graham-Rogers, Harold R. Merwarth, Bernard Stattman, Nunzio A. Rini, Charles E. Scofield, James Steele, Luther F. Warren, F. Edward Jones, Lynn B. Chase, Charles R. Barber, Walter A. Calihan, Edward G. Whipple, Willard H. Veeder, Floyd S. Winslow, Horace M. Hicks, Everett C. Jessup, Louis A. Van Kleeck, Adelbert B. Allen, Emily D. Barringer, Henry W. Cave, Edward M. Colie, Jr., John Douglas, Ten Eyck Elmendorf, Julius Ferber, B. Wallace Hamilton, David J Kaliski, Samuel M. Kaufman, Frederick C. Keller, Samuel J. Kopetzky, Arnold Messing, William M. Patterson, Nathan Ratnoff, Morris Rosenthal, James W. Smith, Frederic E. Sondern, DeWitt Stetten, Joseph Subkis, Henry K. Taylor, Terry M. Townsend, Franklin Welkers, Frederick J. Schnell, Richard H. Sherwood, George M. Fisher, Hyzer W. Jones, Andrew Sloan, William W. Street, Frederick S. Wetherell, Albert G. Swift, Claude C. Lytle, Walter W. Davis, Joseph B. Hulett, Charles E. Padelford, Alva G. Dunbar, Floyd J. Atwell, Carl Goettiger, Edward A. Flemming, L. Howard Moss, James R. Reuling, Jr., Charles B. Story, Albert L. Voltz, Augustus J. Hambrook, John H. Reid, Oscar M. Race, Eugene D. Scala, George A. Leitner, W. Grant Cooper, Stanley W. Sayer, George S. Towne, Dudley R. Kathan, William C. Treder, David W. Beard, Allen W. Holmes, William M. Follete, Leon M. Kysor, Herbert B. Smith, Albert E. Payne, Arthur T. Davis, Luther C. Payne, George M. Cady, Luzerne Coville, Morris Maslon, Walter S. Bennett, Lucius H. Smith, Harrison Betts, Merwin E. Marsland, Romeo Roberto, William J. Doerfler, L. Hayden Humphrey.

The following Officers, Trustees and Chairmen of Standing Committees were present:

William H. Ross, William D. Johnson, Henry L. K. Shaw, Daniel S. Dougherty, Peter Irving, Charles G. Heyd, James Pedersen, John A. Card, Thomas P. Farmer, Frederick H. Flaherty, Arthur J. Bedell, James E. Sadlier, Charles H. Goodrich, Edgar A. Vander Veer, Augustus B. Santry, E. Carlton Foster, W. Ross Thomson, Harry R. Trick, James F. Rooney, Arthur W. Booth, Nathan B. Van Etten, Grant C. Madill.

The following ex-Presidents were present:

Martin B. Tinker, Thomas H. Halsted, Orrin S. Wightman, James N. Vander Veer.

119. Election of Officers

The Speaker announced that the meeting would proceed to the election of officers.

The Secretary announced the following tellers: Edward M. Colie, Chairman, Andrew Sloan, Louis A. Van Kleeck, Reeve B. Howland, Hyzer W. Jones, John Douglas, Aaron Sobel, Augustus J. Hambrook, Charles Leone, John E. Jennings, Walter A. Calihan, and Luzerne Coville.

Dr. Bedell: I move that the election of the Chairman of the Committee on Arrangements be referred to the Council.

Election of Officers

The following officers were elected:

President-Elect, Dr. Charles Gordon Heyd; First Vice-President, Dr. Charles C. Trembley; Second Vice-President, Dr. Harrison Betts; Secretary, Dr. Daniel S. Dougherty; Assistant Secretary, Dr. Peter Irving; Treasurer, Dr. Frederic E. Sondern; Assistant Treasurer, Dr. James Pedersen; Speaker, Dr. John A. Card; Vice-Speaker, Dr. George W. Cottis; Trustee, Dr. Harry R. Trick; Chairman of the Committee on Scientific Work, Dr. Arthur J. Bedell; Chairman of the Committee on Legislation, Dr. Harry Aranow; Chairman of the Committee on Medical Economics, Dr. Charles H. Goodrich; Chairman of the Committee on Public Health and Medical Education, Dr. Thomas P. Farmer; Chairman of the Committee on Public Relations, Dr. James E. Sadlier; Chairman of the Committee on Medical Research, Dr. Stanhope Bayne-Jones.

The following were elected delegates to the American Medical Association for 1932-1933: Dr. Daniel S. Dougherty, Dr. Nathan B. Van Etten, Dr. George A. Leitner, Dr. Samuel J. Kopetzky; Dr. Orrin S. Wightman; Dr. William H. Ross; Dr. James N. Vander Veer.

The following were elected alternates to the American Medical Association for 1932-1933: Dr. J. Richard Kevin, Dr. Charles H. Goodrich, Dr. Emily Barringer, Dr. Edwin A. Griffin, Dr. John H. Reid, Dr. Edward C. Podvin, Dr. Charles B. Story.

120. Saratoga Springs Health Resort

Dr. Towne, of Saratoga: Presented the following:

Whereas, the State of New York has undertaken an extensive program of development for the establishment of a cure resort at Saratoga Springs by means of hydrotherapy through the use of the mineral waters, and

Whereas, the State has already committed itself to this program by the investment of more than five million dollars, and

Whereas, the State Legislature has made a further appropriation of two million dollars for the erection of a research laboratory, drink hall, administration building and other equipment for the operation of the cure régime, and

Whereas, Governor Franklin D. Roosevelt has appointed a reservation commission, whose chairman is Mr. Noyes of Oneida, which is now actively engaged in working out the details of this development and régime,

Be It Resolved, That the Medical Society of the State of New York endorses this program of development by the State, and pledges its support for the success of the undertaking.

The Speaker: Referred to Committee on New Business C. (Sec. 122.)

121. Dispensary Physicians—Remuneration

The Secretary: I wish to read for Dr. Colie, Chairman of Committee on New Business A, the following report: (Sec. 117.)

Whereas, at a meeting of the Coordinating Committee of the Five County Societies of the City of New York, a resolution was offered and passed, that it was the opinion of this Committee that physicians working in dispensaries should receive remuneration, and

Whereas, this resolution was ordered referred to the Five County Society of the State of New York for consideration and action,

Be It Resolved, that it is the sense of the House of Delegates of the Medical Society of the State of New York that Dispensary Physicians should receive remuneration for their services.

I move the adoption of this recommendation.

Motion seconded and carried.

122. Saratoga Springs Health Resort

Committee on New Business C: Approves of the resolution that the Medical Society of the State of New York endorses the development and establishment of a cure resort in Saratoga Springs by means of hydrotherapy through the use of mineral waters.

I move its adoption.

Seconded and carried

123. PRIVILEGE OF THE ASSEMBLY ROOM

Dr. Rooney moved that the House rescind the action taken at the session of June 1 (Section 16), regarding the exclusion from the room of a supporter of a bill adverse to the interest of the medical profession and the welfare of the public.

Motion was seconded and carried.

124. RESOLUTIONS OF THANKS

The Secretary: I move that a vote of thanks be extended to the Committee on Arrangements and its subcommittees, together with the Onondaga County Medical Society for their hospitality and courtesy in furnishing entertainment for the members of the Society and for the attention and efficiency in which they have conducted all the arrangements for the meeting.

Seconded and carried.

The Speaker: Members of the House of Delegates, we are about to conclude our deliberations. Mr. Secretary, is there anything left undone?

The Secretary: Nothing to my knowledge.

Dr. Rooney: I move this House adjourn sine die.

The Speaker: I declare the 125th meeting of the House of Delegates adjourned without date.

JOHN A. CARD, *Chairman Speaker*
DANIEL S. DOUGHERTY, *Secretary.*

BROOME COUNTY

The regular monthly meeting of the Broome County Medical Society was held on May 29, 1931, in the Art Gallery at the Hotel Arlington. Dinner was served at 7 P. M. About fifty members were present.

Dr. Victor W. Bergstrom of the Kilmer Pathological Laboratory, and Dr. Katherine B. McInnis of 120 Oak Street, Binghamton, were elected to membership; Dr. C. E. Rowe, of the Syracuse State School, was reinstated; and Dr. Mark W. Welch, of 207 Washington Street, Endicott, was proposed for membership.

A letter was read from Dr. E. S. Steblen, Secretary of the Binghamton Psychiatric Society inviting the Broome County Medical Society to be its guest at the Spring Meeting which is to be held on June 15th at the Binghamton State Hospital.

A communication was read from Senator Love in which he expressed his appreciation of a letter from the Broome County Medical Society complimenting him on his attitude towards the chiropractic and the osteopathic bills. Dr. Love further said in his letter that the Senators expected the medical profession to offer some constructive program.

The scientific program consisted of addresses by Dr. George E. Bennett, Professor of Orthopedics, Johns Hopkins University, Baltimore, Md., and Dr. Sydney R. Miller, Internist of Johns Hopkins and Union Memorial Hospitals, Baltimore, Md. Dr. Miller spoke on "Blood Stream Infections and Their Therapy." This title Dr. Miller said was a misnomer which he used purposely. Dr. Miller described the invasion of the body by infection as a trench warfare. He spoke at length on the various infections, their treatment, vaccines, and transfusions. The paper was most instructive and interesting and was highly appreciated by those present. The paper was discussed by Drs. George Bennett, C. M. Allaben, W. H. Hobbs, C. D. Squires, H. L. Johnston, U. S. Kann, F. M. Dyer, D. Molyneaux, S. H. Kinne and C. H. Berlinghof.

Dr. Bennett spoke on "Stiff and Painful Shoulders," and discussed the symptoms, differential diagnosis and treatment. The address, illustrated by lantern slides, was a most interesting one, splendidly presented, and greatly enjoyed by all present. It was discussed by Dr. Mary J. Ross, Dr. C. M. Allaben, Dr. W. H. Hobbs, and U. S. Kann.

HENRY D. WATSON, *Secretary.*

FRANKLIN COUNTY

The regular semi-annual meeting of the Medical Society of the County of Franklin was held in the John Black Memorial Room in Saranac Lake, June 10, 1931 A noon luncheon was served at Hotel Saranac, and a Business Session began at 2 P M

The following officers were present

Dr P E Stamatiades, President, in Chair
Dr H Beattie Brown Vice President
Dr G F Zimmerman, Secretary and Treasurer
Dr R G Perkins, Censor

Members present were Drs D M Brumfiel, E M Jameson, J F Eagan, F H Heise, E N Packard, H McL Kinghorn, J W Kissane, E S Welles, C C Trembley, J N Hayes and M A Wardner

Drs Kissane, Kinghorn and Packard were named a committee to nominate officers for the coming year

The following nominations were submitted and unanimously approved

For President, Dr H Beattie Brown
For Vice President, Dr J W Kissane
For Secretary-Treasurer, Dr G F Zimmerman
For Censor, for three years, Dr E M Jameson
Delegate to New York State Meeting Dr C C Trembley
Dr Robert J Beck was elected to membership

The business session was unusually active and many helpful suggestions were made and accepted

Dr C C Trembley reported the proceedings of the New York State meeting for 1931, which he attended as delegate, and stated that the meeting was uniformly harmonious and that in the main only routine work was accomplished (Dr Trembley had been elected first Vice President of the State Society)

It was regularly moved, seconded and carried that Dr Trembley and Dr Welles be added to the committee appointed by the Malone Staff of Physicians to confer with the Supervisors of Franklin County in an effort to secure payment for physicians' services rendered town and county cases under hospitalization The other members of the Committee are Drs Perkins, White and Welding

The fee suggested by the Workmen's Compensation Commission was adopted. It was regularly moved, seconded and carried that the President name a Public Relations Committee to arrange for pre-school clinics for Franklin County in those districts where clinics are not already held

Dr. Perkins, Chairman of the Cancer Committee, reported that he found many people who are eager to learn about cancer, and advised that at some time in the future considerable time should be given at one of our meetings to the subject of cancer Much discussion was given to the subject of physicians and surgeons services to county patients under hospital care, and all agreed that such services should be paid a reasonable amount

The scientific session was one of unusual interest, the papers all being of present-day progress, and carefully prepared

1 Common Fractures of the Spine and Their Treatment—Dr R G Perkins, Malone

This lecture was graphically illustrated by the use of X-ray plates and a cleverly assembled spinal column showing the mechanical events in the course of a fracture

2 Allergic Manifestations in Infants—Dr J W Kissane, Malone

This paper showed in a lucid manner the factor of diet in the prevention and cure of some of the alarming allergic explosions in the infant

3 Acute sub-clavicular infiltration—Dr J N Hayes, Saranac Lake

This was a highly instructive paper, illustrated by X-ray plates, showing the great importance of X-ray pictures in all cases of suspected tuberculosis of the lungs These X-rays frequently reveal active tuberculosis before any definite physical signs can be elicited

G F ZIMMERMAN,
Secretary

TRI-STATE CONFERENCE

Two representatives from New York, Drs Ross and Lawrence, participated in the eighteenth session of the Tri State Conference which was held in Philadelphia on May 23, 1931 Seven representatives were present from Pennsylvania and four from New Jersey

The program consisted of two papers Dr Ross I Patterson, of Philadelphia, President of the Medical Society of the State of Pennsylvania, spoke on "Our Responsibility for Public Education Regarding Comparative Costs of Sickness", and Dr Walter F Donaldson Secretary read a paper on "A Romance of Paternalism, referring to wastefulness in the treatment of war veterans Every representative present contributed to the discussion

GREENE COUNTY

The regular meeting of the Greene County Medical Society was held on May 18 at the Saulpaugh Hotel, Catskill. The Scientific session at 8 P. M. was preceded by a dinner.

Dr. Atkinson, the President, presided and the following members were present: Drs. Van Hoesen, Daley, A. O. Persons, Rapp, Honeyford, Waller, Van Slyke and Goodrich.

Dr. Thomas P. Farmer of Syracuse, Chairman of the State Committee on Medical Education; Dr. Edgar A. Vander Veer of Albany, President of the Third District Branch; Dr. Joseph Lawrence, Executive Officer of the State Society, and Mr. Henry Barker, Welfare Commissioner of Greene County, were guests.

Dr. Thos. E. McQuade of Coxsackie was proposed for membership.

A communication from Dr. Chandler, Chairman of the State Committee on Medical Economics, was read regarding an agreement between the insurance carriers with reference to fees for compensation cases. It was discussed by Drs. Honeyford, Rapp, Van Hoesen, Daley, Atkinson, Vander Veer and Lawrence. No formal action was taken.

Dr. Thomas P. Farmer then gave an interesting address on Cancer of the Female Generative organs and illustrated it by lantern slides.

At the request of the President Dr. Farmer at the conclusion of the discussion of his paper gave a resumé of what he had learned in his journeys about the State about County Health units.

Mr. Barker was next introduced and spoke on the administration of the Public Welfare Law in Greene County. This was discussed by a number of members and it seemed to be the opinion that we had a very able and conscientious Commissioner who was always ready to co-operate with the physicians.

A vote of thanks was given Dr. Farmer and Mr. Barker.

Dr. Daley, Chairman of the Committee on Public Relations, appointed Drs. R. F. Persons, Rapp, Van Hoesen and Sinclair as members of the Committee.

Dr. Goodrich moved that an assessment of $1.00 per member be levied to provide a gift for Dr. Willard on the completion of 40 years services as Treasurer of the Society. Seconded by Dr. Van Hoesen and carried. Drs. Honeyford, Rapp and the President were appointed to carry out this plan.

W. M. RAPP, Secretary.

ALLEGANY COUNTY

A luncheon and regular meeting of the Allegany County Medical Society was held at the Wellsville Country Club, May 28th, 1931, with the President, Dr. H. K. Hardy, in the Chair.

Papers by Dr. Douglas P. Arnold of Buffalo upon "Gastro Intestinal Disorders in Childhood" and Dr. J. Paul Rems of Belmont upon "Precardial Pain" were read and widely discussed.

It was voted that the delegate to the State Society be instructed to oppose any action of the State Society tending to favor any bill in the state legislature making compulsory the establishment of County health units.

Resolutions of regret and respect were adopted regarding the recent deaths of Dr. W. R. Harbison of Bolivar, and Dr. B. C. Wakely of Angelica.

Doctors Ethel B. Perry and Dorothy Gray of Belfast were accepted as members of the society.

LYMAN C. LEWIS, *Secretary.*

LEWIS COUNTY

A regular meeting of the Medical Society of Lewis County was held at the Carlowden Country Club, in Denmark, N. Y., on May 12th.

We gladly welcomed several members of the Jefferson County Medical Society who accepted the invitation to meet with us and hear Dr. Frederick S. Wetherell of Syracuse, N. Y., who presented the topic "Diseases of the Thyroid Gland" in such an interesting, instructive and conversational manner that none were cognizant of the passing time.

We take this opportunity to thank the members of the Jefferson County Medical Society for their thoughtful interest in our small medical organization, shown by inviting us to and making us feel at home at, their yearly post-graduate lecture courses.

F. E. JONES, *Secretary.*

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall, on May 20, 1931, was called to order at 9 P. M., with the President, Dr. Gettinger, in the Chair.

The following candidates were elected to membership: Drs. Solomon P. Carp, Arthur F. Donofrio, Aaron M. Lefkovits, Hymen J. Mendelowitz, S. Jerome Rauch, Nathan Savitsky, and Charles Weinreb.

The Economic Program proceeded as follows:

Address:

"The Whys and Wherefores of Compulsory Health Insurance," Hon. Julius S. Berg, Senator —State of New York.

Discussion:

Dr. Linsly R. Williams, Director—New York Academy of Medicine.

Dr. Nathan B. Van Etten, Ex-President—Medical Society of the State of New York and Bronx County Medical Society.

Dr. Louis I. Harris, Former Health Commissioner—City of New York.

I. J. LANDSMAN, M. D., *Secretary.*

The Annual Meeting of the Bronx County Medical Society was held at Elsmere Hall, 170th Street at College Avenue, on June 17, 1931, with the President, Dr. Gettinger, in the Chair.

Drs. Aaron Herzog, Harold H. Levy, Nathan H. Rappaport and Isaac Schultz were elected to membership.

The following officers were elected for the ensuing year:

President ..... Irving Smiley
First Vice-President ..... William Klein
Second Vice-President ..... Maurice O. Magid
Secretary ..... I. J. Landsman
Treasurer ..... J. Adlai Keller

Board of Censors: Joseph H. Gettinger, Joseph Golomb, Milton J. Goodfriend, Edward R. Cunniffe, Harry Projector, Adolph Rostenberg.

Delegates: J. Lewis Amster, Edward R. Cunniffe, Cornelius J. Egan, Vincent S. Hayward, Harry Aranow, Louis A. Friedman, J. Adlai Keller, Edward C. Podvin.

Alternates: Benjamin Diamond, Samuel Feldman, Moses H. Krakow, Isaias A. Lehman, William Lenetska, Louis Nagorsky, Charles S. Rogers, Samuel Rosenzweig.

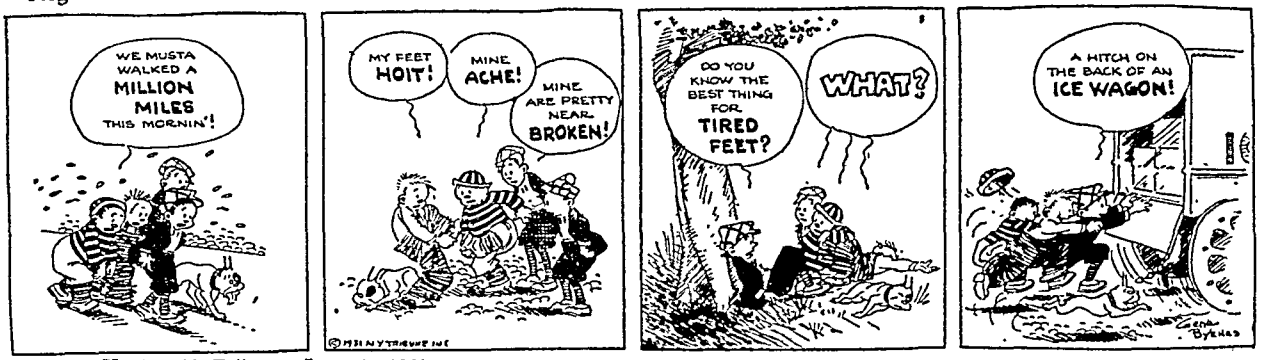
Resolutions on the death of Dr. J. B. Cohen, a charter member of the Society, were adopted by a rising vote.

Dr. Magid, for the Committee on Medical Economics, reported as to Hearings of the Labor Department on Compensation Cases and of the Arbitration Committee.

Dr. Aranow, Chairman of the State Legislative Committee, reported as to the advisability of our Society opposing those legislative candidates who have supported bills against the interests of the public health.

Dr. L. A. Friedman, Chairman of the Committee on Public Health and Medical Education, reported that the Committee, in conjunction with the Bronx Tuberculosis and Health Committee, has been making every effort to have the examination of school children done by the family physician instead of the school doctor. The Department of Education is cooperating in our endeavors to send letters from each of the public and parochial schools of the Bronx urging the parents to take their children to their physician for examination before admission to school.

Dr. Benjamin introduced a Resolution endorsing the Schedules of Salaries submitted by the Public Health Officers' Association of the City of New York requesting increases to Clinic Physicians, Medical Inspectors, Dentists, and Veterinary Surgeons in the service of the Department of Health. This Resolution was put to vote and was unanimously adopted. The Secretary was instructed to communicate with the Mayor, appealing for the approval of the Board of Estimate and Apportionment.



The scientific program of the evening then proceeded as follows:

1. "Contributions of Medical and Other Sciences," Joseph H. Gettinger, Retiring President.
2. "Tibet—The Forbidding Forbidden Land" (Illustrated with Motion Pictures), Gene Lamb.

I. J. LANDSMAN, M.D., *Secretary*

THE DAILY PRESS

Reg'lar Fellers — Very Soothing — By Gene Byrnes

From N. Y. Herald Tribune, June 1, 1931.

TEACHING HEALTH BY EXAMPLE

Instruction in the theory of health is obligatory in the public schools of New York State, but teaching health by practice is voluntary. The New York Sun of June 8 has the following editorial comment on conditions in the schools of New York City:

"New York city's school masters and mistresses instruct their pupils in hygienic habits. But the city does not practice what the instructors preach; a student on his way from a class in 'health education' to the lunch room can find no facilities for washing his hands. The Board of Education, for reasons of economy, supplies neither soap nor towels; in the few schools where these are available, the cost is borne by the parents' association or some similar organization.

"This condition will be remedied, however, if the school board follows the counsel of the Board of Superintendents, which has recommended that the budget for next year include an appropriation for soap and paper towels for all schools. 'Handwashing facilities,' reads the recommendation of the superintendents, 'are as essential and justifiable in any school as are books, paper and pencils.'

"Installation of soap and towel service in the public schools has been advocated for years. The latest mention of the matter was made a few days ago by the Joint Committee on Education, which reported on conditions in the Harlem schools. Medical societies, parents, teachers and principals have protested that the entire health education program in the schools was at times vitiated because children had no means for washing the dust and grime of the classroom from their hands.

"The stock answer has been that the children would waste the paper towels. Accordingly, experiments have been carried on with hot-air drying apparatus. To install such apparatus in old schools, however, would probably be more expensive than to distribute paper towels. As for waste, it is estimated that the proposed service would cost $60,000 a year; the entire sum could easily be saved by watchfulness in the purchase of but one school site a year."

THE NEW YORK HOSPITAL

The New York Hospital will be the nucleus for the new Cornell Medical Center, just as the Presbyterian Hospital is for that of Columbia. The New York Times of May 27 says editorially:

"The New York Hospital, which has been from its foundation, in 1791, a teaching hospital, is at the threshold of one of the most stupendous undertakings for the sick and for teaching and medical research. Its majestic new buildings, filling three blocks immediately north of the Rockefeller Institute for Research, between Sixty-eighth and Seventy-first Streets, and rising like white cliffs from the edge of the East River, are as mighty a fortress against disease as is the Medical Centre on the west

side of the island. The part-time staff will be composed of men who are also in private practice and are considered essential both in their linking the hospital to the community and to the general practice and in their influence upon the full-time members and the students. Their professional attainments and their value as teachers will determine their appointment.

"'The Mother of Hospitals' is thus in its varied service to continue to hold the place in the community which age alone could not have assured it. The generous gifts of many have helped to make the physical provision possible; but, except for the deep interest and foresight and the munificent legacies of the late Payne Whitney, what is now a certainty could hardly have been more than a hope or a remote possibility."

STANDARDIZING DOCTORS

The following editorial from the *New York Herald Tribune* of May 27 will be approved by family doctors:

"The idea that the family physician is being squeezed out of existence by the specialist on the one hand and group practice on the other has been answered very effectively in a speech to the Medical Society of the County of New York by Dr. Wingate M. Johnson, of Winston-Salem, N. C. It is an idea which stems from the notion that standardization, the watchword of modern civilization, can be stretched to include personal service as well as commodities. Dr. Johnson, in dispelling it, puts the community under obligation to his common sense. Here is the gist of his argument:

"The basic defect in comparing the medical profession with merchants and manufacturers is that doctors are dealing with human beings rather than machines; and human beings are individuals and simply refuse to be standardized. The parts of one Ford car will fit a million other Fords; but no two human beings are exactly alike. To overlook the human equation and attempt to treat people as animated machines is to invite failure.

"In other words, no doctor can fulfill his function unless he knows his patients intimately, since each, whatever his ailment, presents a problem by itself. The specialist, to be sure, has his place as an authority in a narrow field who is valuable as a supplement to the general practitioner. So have those institutions or corporations, public or private, to which certain categories of invalids may repair for treatment as to a cafeteria. But the bedrock of the profession will still continue to repose in those devoted men who make it their business in life to minister to individuals regardless of what ails them.

"The truth of Dr. Johnson's remarks is not confined to the practice of medicine. Personal idiosyncrasy has set a limit to standardization beyond which it ventures at its peril. This limit may vary with the type of service involved, but even the merchant and the manufacturer have been made aware of it. The individual is still supreme in the world, and long may he wave!"

A NEW BEEF ANIMAL

The people of the United States are becoming accustomed to reindeer steaks from Alaska, and now they may possibly be offered meat from a new hybrid animal. *The New York Times* of May 26 says:

"When the animals marched into the ark two by two there was not a galoyak in the line-up. His absence, however, was no reflection on his value, for that historic launching took place before his time. He is a parvenu of such recent date that he has not even yet made his appearance in cross-word puzzles. But he is so valuable that, since no galoyak existed, one had to be invented.

"He is a scion of the Yak family, and of truly eugenic breeding. Yaks have long flourished in subarctic regions, leading satisfactory lives except for the fact that they do not provide appetizing food for subarctic peoples. In Canada the experiment was made of mating them with buffaloes, but their progeny still made tough eating. Later, in Alaska, the experts evolved a scheme for inter-marriage between yaks and Galloway cows. The resulting hybrids were a huge success. The young galoyaks have the stamina to withstand the rigors of the cold climate, and also provide tender cuts of meat for Alaskan dinner tables."

BOOK REVIEWS

COAL-MINERS' NYSTAGMUS. By G. F. HAYCRAFT, M.R.C.S., L.R.C.P 12mo of 15 pages. New York and London, Oxford University Press, 1931. Paper, 30c. (Oxford Medical Publications.)

Here is a little monograph dealing with the practical aspects of miners' nystagmus. It is evidently written by a man who has had experience. The English ophthalmologists seem to have coal-miner nystagmus experiences quite often. We do not. It is doubtless because we do not have so many of these cases even in the great coal mining regions. There have been a number of studies on the subject during the last year or so and in fact, the Government is exercising every effort to help out the workers. In some sections of Great Britain there has been an increase in the number of nystagmus cases.

While we do not expect to see many or any, for that matter, of these eye-jumps, it is well for ophthalmologists and neurologists to peruse the 15 small pages of this booklet, for it will give them ideas for differential diagnosis. We all need ideas. J. N. EVANS.

ROENTGEN INTERPRETATION: A Manual for Students and Practitioners. By GEORGE W. HOLMES, M.D., and HOWARD E. RUGGLES, M.D. Fourth edition. Octavo of 339 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $5.00.

This book has met with such generalized success that within a comparatively short space of time the fourth edition now appears. It is written essentially for beginners and has been brought up to date, keeping pace with the ever-advancing science of Radiology that has now become such an absolute necessity for modern diagnosis. Any skilled technician can take radiograms, but only a well trained, experienced roentgenologist can interpret them properly. Better no radiologic study at all, than an incorrect interpretation.

The authors specifically state that no attempt was made to cover the subject completely, but rather to suggest and illustrate key cases to whet one's appetite for more thorough knowledge of such subject or subjects in which the particular individual is interested.

A thorough bibliography completes each chapter, the running down of which will more than satisfy the most zealous mind.

For a general survey of the subject, teaching purposes, and a lead for more detailed knowledge, one needs to look no further. Students and beginners will find a mine of information and the more experienced can readily brush up with its aid.

MILTON G. WASCH.

A TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY. By JOHN GLAISTER, M.D., D.P.H., in collaboration with JOHN GLAISTER, Jr., M.B., Ch.B. Fifth edition. Octavo of 954 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $8.50.

This book is a real delight to anyone interested in this subject; and considering the scope of the topics discussed, it could not fail to be of value to every physician. Under examination, there is a very illuminating article on finger printing, not found in all books on this subject. Two other chapters of marked scientific interest which are extremely well presented are death by suffocation, and by electricity and lightning. The part of the book dealing with toxicology gives all the information that any physician would desire.

J. F. W. MEAGHER.

INDUSTRIAL MICROBIOLOGY. The Utilization of Bacteria, Yeasts and Molds in Industrial Processes. By HENRY FIELD SMYTH, M.D., and WALTER LORD OBOLD, M.S. Octavo of 313 pages. Baltimore, Williams & Wilkins Company, 1930. Cloth, $6.00.

In this volume the authors have assembled an immense amount of practical information on the use of bacteria, yeasts and molds in industry. It is a working manual for the industrial bacteriologist. To the physician and the student of human pathogens, it will be of no practical value but a reading of certain portions will add to one's general knowledge, bring to light many curious facts and make one realize the vital role of micro-organisms in many industries and in the life cycle of man.

The authors discuss the part played by micro-organisms in the production of vinegar, lactic acid, various alcohols, glycerine, glue, gelatin, tanning of hides, preparation of such textiles as rayon and flax, ensilage and preservation of sugar, curing of tobacco, solidifying of rubber latex and commercial enzyme manufacturing. They also discuss the harmful effects of micro-organisms in spoilage and shrinkage of many products including foods. They give complete technical directions for work in industrial microbiology including a discussion of patents.

Micro-organisms seem to play an important part in nearly all industries with their possibilities not yet fully exploited. Among the curious facts found in this book were the following: cigarettes consist exclusively of fermented tobacco; Charlotte, N. C., operates motors with gas formed by fermenting sewage and progressive New Castle, Pa., makes gas for heating in the same way.

E. B. SMITH.

EPIDEMIOLOGICAL ESSAYS. By F. G. CROOKSHANK, M.D., F.R.C.P. Octavo of 136 pages. New York, The Macmillan Company, 1931. Cloth, $2.50.

In this book Dr. Crookshank has attempted to play the role of a philosopher. First, speculating on a problem about which we often wonder but into which we never delve, namely, Why Time Flies,—he later deals with the more familiar topic of watering places and climates for the treatment of disease and while he does not enumerate the distinctive virtues of this supplemental branch of medical therapy he implores his medical readers to be tolerant with such empiricism which he places on a par with cinchona in the treatment of malaria and its derivative, quinidine, for heart disease. He concludes this chapter by reminding us that "the laboratory by itself is bound to fail . . . but when we do prosecute observations in the field of Nature we are not quite so confident of attaining ultimate explanations as are our valued colleagues of the laboratory."

He discusses some practical problems of influenza by stressing on the telluric and cosmic influences which he considers to be quite as important as the microcosmic standpoint in the interpretation of that disease. There is a chapter on the treatment of encephalitis lethargica which tells us about everything that could be done for the patient except the specific agent about which we do not know. And after this energetic but futile dissertation he concludes that it "would be foolish to give any statistical impressions of the results of treatment conducted on these lines."

The chapter on pneumonia is very short but especially interesting because it depicts a distinct change in the trend of medical practice. He maintains that the "average case of pneumonia, influenzal or otherwise, was better and more wisely treated on the whole thirty years

ago than today ' because in those days the importance of the individual was paramount while today we deal in groups or in statistics It is not uncommon for the present day physician after diagnosing an ailment as pneumonia to find the patient shipped to a hospital on the advice of neighbors or friends with the consequent added danger due to transportation as well as the inherent increased hospital mortality rate as compared to the home to which one has been accustomed

EMANUEL KRIMSKY

MICROBIOLOGY AND ELEMENTARY PATHOLOGY For the Use of Nurses By CHARLES G SINCLAIR, B S, M D Octavo of 362 pages, illustrated Philadelphia, J A Davis Company, 1930 Cloth, $2 50

Those who have had experience teaching nurses pathology and bacteriology realize the need for a text book which will give a 'suitable perspective of these subjects" and yet not burden the student with the ' frightening depths of the average medical text-book

In the opinion of the reviewer this book is answer to the call Parts I and II deal with microbiology, presented in a concise, practical and comprehensive style The insertion of laboratory methods of diagnosis of each organism under consideration and the vivid illustrations each of which tells the story of the pathology produced by these organisms amplifies the long descriptions given in other texts These features induce receptivity on the part of the student nurse who would otherwise be bored by long chapters of reading matter

The laboratory exercises undoubtedly convert the subject matter which would otherwise appear to the student as an abstract philosophy into a practical subject.

Section III, on Elementary Pathology, deals with representative pathological processes which are essential for the student nurse This section includes clinical pathological methods with which the nurse should become acquainted in order to properly equip herself for her duties in medicine A better text book cannot be found on the library shelf of a nurse's home

SILIK H POLAYES

A HANDBOOK ON DISEASES OF CHILDREN including Dietetics and the Common Fevers By BRUCE WILLIAMSON, M D M R C P 12mo of 290 pages, illustrated New York, William Wood & Company, 1931 Cloth, $3 50

This is a compend on diseases and conditions that affect infants and children

Only a few paragraphs are given on each subject—in fact a few pertinent facts as to onset, symptoms, diagnosis and treatment

It is really too brief to be of practical value to a well trained physician whose practice includes infants and children T B G

INFANT FEEDING IN GENERAL PRACTICE. By J V C BRAITHWAITE M D, M R C P 12mo of 140 pages New York, William Wood & Company, 1930 Cloth, $1 75

This little book, as its name implies is written for the general practitioner and contains much sound advice

The emphasis laid on breast milk feeding throughout the book is unusual, and may well be taken as a model for many of us to follow

The basic elemental figures for computing modified milk formulas correspond very closely to the American method In fact, they have their origin from America

There is much common sense reasoning and one who follows the advice cannot go far wrong

It is brief, sound, and well worth while

A D SMITH

THE TREATMENT OF CHRONIC DEAFNESS by the Electrophonoide Method of Zund-Burguet By GEORGE C CATHCART, M A M D Second edition 12mo of 111 pages, illustrated New York and London, Oxford University Press, 1931 Cloth, $1 50 (Oxford Medical Publications)

One of the most discouraging phases of otologic practice is the treatment of chronic deafness, especially the type due to auditory nerve disease Dr Cathcart describes in an able and convincing manner his experiences with 665 cases treated by the Zund-Burguet method during a period of seven years and states that 65% of his cases have been improved He does not speak of cures but of functional improvements especially in stubborn forms of accompanying tinnitus The instrument employed is an electrical device known as an electrophonoide which by reproducing as far as possible the same kind and number of vibrations as are contained in the whole range of human voices electrically re educates the ears with the sounds of the human voice

He offers no logical explanation for the beneficial effects by this method of treatment but asserts that it is as empirical as the use of quinine in malaria

The treatment of chronic deafness has been such a disheartening phase of otological practice that some encouragement in the form of such a treatise should serve as a welcome tool for further experimentation How often we find such helpless individuals subjected to frequent Eustachian tubal inflations to nose and throat operations, or to removal of questionable foci of infections with not the faintest iota of relief

EMANUEL KRIMSKY

MODERN METHODS OF TREATMENT By LOGAN CLENDENING, M D Fourth edition Octavo of 819 pages, illustrated St Louis, The C V Mosby Company, 1931 Cloth, $10 00

In this fourth edition, the first published in 1924, the plan of the book is the same, that is, to furnish an outline of all the methods of treatment used in internal medicine The first part deals with general therapeutics and the various methods of treatment, as those which employ drugs, diet, hydrotherapy, electrotherapy and other procedures

The second part on special therapeutics describes the application of the various methods of treatment to specific diseases

Some additions in this edition are the description of the use of desiccated stomach in pernicious anemia, of salyrgan, undulant fever, the use of parathyroid hormone in Paget s disease and of hyperparathyroidism

The book is convenient in its inclusion of many subjects not ordinarily found in one volume and the author has an original style of writing which is easy to read

W E McCOLLOM

A TEXTBOOK OF LABORATORY DIAGNOSIS with Clinical Applications for Practitioners and Students By LEWIS E OSGOOD, M A, M D, and HOWARD D HASKINS M D Octavo of 475 pages, illustrated Philadelphia, P Blakiston's Son & Co, Inc, 1931 Cloth $5 00

Laboratory Diagnosis" by Osgood and Haskins is a relatively short and comprehensive volume, intended to arouse the interest of the student, and to satisfy the needs of the practitioner in this field of medicine It expresses the views of the authors as taught at the University of Oregon The book is divided into two parts the first of which concerns itself with explanation of the theoretical foundations of laboratory diagnosis as applied to the various systems, the second is devoted to a technical description of the tests recommended The book is well illustrated As a whole the subject is handled efficiently, and should prove to be of value to both the student and practitioner

MAX LEDERER

OUR NEIGHBORS

MEDICAL TRENDS IN SOUTH CAROLINA

The modern tendencies in the practice of medicine are under discussion in every State Medical Society, and are frequently the subject of Presidential addresses. An excellent discussion of the subject is that of Dr. Kenneth M. Lynch, President of the South Carolina Medical Association given before the annual meeting on May 6, and reported in the May issue of the Journal of the State Association.

Doctor Lynch first refers to a definition of the field of medicine adopted by the British Government:

"Medicine deals not only with the cure of disease, but also with the proper development and right use of the human body in all conditions of activity and environment, as well as with its protection from disease and accident, and its repair."

Discussing the importance of curative medicine, Doctor Lynch says:

"At the same time that we have been actively reducing the number of diseases to be cured, we have been increasing the volume of measures to be used against those which now remain, to such an extent that curative medicine is now of much larger proportions that it ever was. . . . So far as the main body of the profession is concerned, curative medicine is, and will probably remain indefinitely, the major activity in medicine.

"The truth of this conception of curative medicine is not altered by the fact that some of the major troublesome problems which confront us today concern this field. . . . . We have encountered economic problems which are not solved to the liking of the profession or the public, and about which we are being harassed by those who would solve them for us on grounds which do not take the special character of service into account and which, therefore, are not only not acceptable but are at times provocative of resentment."

Discussing the practice of preventive medicine, Doctor Lynch says:

"Turning to the main consideration in the British government's definition of medicine—that it deals with the proper development and right use of the human body in all conditions of activity and environment, as well as with its protection from disease and accident, and its repair—we find reason for deep concern as to how the profession is to keep control of the broad field if this definition is to become of practical acceptance, as it apparently must.

"Within this lies a conception of a spread of preventive medicine to boundaries heretofore largely unthought of and probably not now to be visualized. I need only to refer to two largely uncultivated fields, those of the sciences of nutrition and of psychiatry, to bring to mind the wealth of ignorance in the very fundamentals of the preservation of health of the body and the mind with which we are still surrounded.

"At the present time we think of preventive medicine largely in terms of breaking the chain of sequence in the transmission of infection—and we have been disappointed many times in its impracticability. We have had only an occasional glimmer of light on the prospect of something farther back, something nearer basic than that, in controlling infectious disease. We have also vaccinated against the contraction of infection, and are still in trouble to make our vaccinations acceptable by the people.

"Our knowledge of the relation between malnourishment and disease is not such that we can speak with certainty even about those conditions, such as scurvy and rickets, concerning which we commonly express ourselves so confidently. To speak of feeding in its relations to other major conditions of disease which might be named or even to the control of structural development of the human being is only justifiable at the present in an acknowledgment that they are at least related in our ignorance of their fundamentals. When we call to mind the fact that the honey bee can vary the treatment, apparently the feeding, of its larval young so as to develop at will a fully matured female organism in the queen bee on the one hand or an unsexed female worker on the other, it is not unscientific to speculate on what the human might do in assuring proper conditions for developing its young and preventing the occurrence of deformities and of weaknesses during intra-uterine life. Pre-natal care, when attended to at all, is now constituted largely in the interest of the mother, that she may carry on through the period of pregnancy and delivery in a healthy state. In the scheme of nature normal motherhood is an incident in the main event of the production of fit offspring, and pre-natal care will come to have more reference to the proper condition of the child for its entry into the external world.

"It is particularly appropriate that such matters should be called to mind here for the purpose of recognizing the public participation which this State has undertaken in the study of nutrition; and that complacency in the Profession might well lose to it the guidance which should be in our

(*Continued on page* 856—*adv. xiv*)

IN INFANT FEEDING

if you are using lactic acid milk

Dextri-Maltose *is the* Carbohydrate *of* Choice

because it is dry, easy to measure, bacteriologically clean, unattractive to flies and dirt, being prepared exclusively for pediatric use by a natural diastatic action instead of an acid hydrolysis process. Moreover, long clinical experience indicates that Dextri-Maltose is the most easily assimilable of all carbohydrates, least likely to cause nutritional disorders.

For the convenience of physicians who desire to employ lactic acid milk with Dextri-Maltose, there is available

MEAD'S POWDERED Non-Curdling LACTIC ACID MILK
NO. 1 (with Dextri-Maltose)

This product offers several practical advantages: (1) It is more simply prepared for the mother than fluid lactic acid milk—with less danger of error (2) It is uniform in composition. (3) It is practically sterile, but may be boiled without curdling. (4) It is economical because there is no waste. (5) It is convenient for the traveling mother, as no refrigeration is required

For physicians who appreciate the advantages of the powdered form over the fluid form of lactic acid milk, but who prefer to make their own carbohydrate additions, there is also available

MEAD'S POWDERED Non-Curdling LACTIC ACID MILK
NO. 2 (without Dextri-Maltose)

These three Mead infant diet materials are for sale at drug stores —without dosage directions and are advertised only to physicians.

Mead Johnson & Co. SPECIALISTS IN INFANT DIET MATERIALS **Evansville, Ind., U.S.A.**

Collosol ARGENTUM

(CROOKES)

A stable and uniform suspension of colloidal silver 1-2000

ADVANTAGES

Non-irritating.
Isotonic with the blood.
Deeply penetrating.
Does not stain the tissues.
May be boiled without precipitation.
In liquid form, ready to use.
No dissolving, no diluting.

CONCENTRATED POLLEN ANTIGEN

LEDERLE

RAGWEED COMBINED

For Fall Hay Fever

90% of all Hay Fever east of the Rocky Mountains is caused by the Ragweeds, Giant and Small. Thus the Hay Fever problem is simplified for the practising physician within this territory.

For the further convenience of the physician, Concentrated Pollen Antigen (Lederle) Ragweed Combined is now available in individual-dose syringes serially numbered. Each syringe contains an accurately measured dose ready for subcutaneous injection without dilution.

For 17 years Pollen Antigens Lederle have been successfully employed by general practitioners in the prevention and treatment of HAY FEVER.

Concentrated Pollen Antigen (Lederle) Ragweed Combined, *For Use Without Diluting*, is prepared by extracting the pure, mature pollen grains of Ragweed and Giant Ragweed 66⅔% glycerol and 33⅓% buffered saline solution. The extracts contain 0.4% phenol as a preservative. The individual-dose syringes are filled with an 0.2 cc. volume and permit the accurate injection of the entire dose or such division of the dose as may be desired. In these small doses, the 66⅔% glycerol with 33⅓% buffered saline may be injected subcutaneously without producing undesirable reactions.

Literature based on seventeen years experience and covering the main features of the Hay Fever problem will be furnished physicians upon request.

We also invite correspondence upon specific cases in any locality.

LEDERLE LABORATORIES Inc. NEW YORK

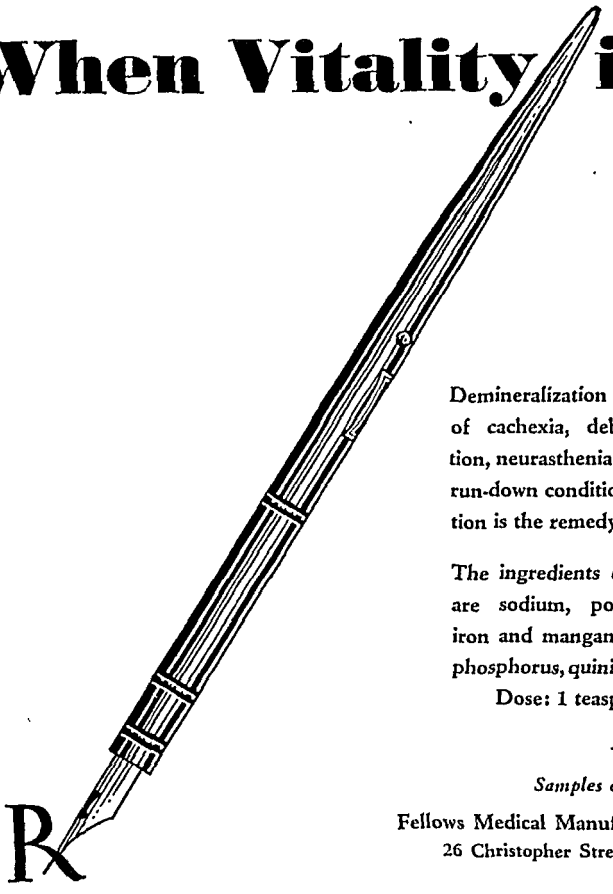
(*Continued from page* 854)

hands, might even nullify this splendid beginning or cause it to be side-tracked into unworthy channels in which its scientific purpose would be vitiated or destroyed.

"In the large territory of mental hygiene we have made so little progress that there are not more than a figurative handful of us who even understand the language of the few who have undertaken to enter it."

"To enter into further discussion of these and of other major problems, such as the influence of heredity, or the menace of cancer, perhaps might create an impression of pessimism contrary to a real feeling of optimism about the outcome which is as certain as it is that the profession is the agency responsible for the prolongation of life of our young through a more healthy and happy duration in the present generation over the past

"That there is any serious disposition to disturb the control of the whole of medicine by the profession I sincerely doubt. There is, however, an intense and growing interest in the public and in various agencies of it to bring about more activity in solving the live problems both professional and economic, of preventive and curative medicine. Failure on our part to take the directing lead or to give evidence of full cooperation in these movements has been and will be taken as selfish or headstrong balkiness.



"Failure of leadership or blunt disagreement will take control out of our hands and will no only allow, but will demand, an extension of public medicine. The exhibition of a spirit of guiding cooperativeness should preserve our position of medical advisor and supervisor.

"That socialization of medicine in some form and to some extent seems inevitable to close students of the present trend is apparent. That it is the bugaboo which some profess to see, is not necessarily true. Whether it may be or not is dependent on the participation of the profession.

"We can visualize one form of 'state medicine' in which individual effort would be stifled and the progress of medicine stringhalted. Another kind can be visualized in which progress in knowledge and ability of the individual and of the whole would be stimulated.

"Take a page from military annals, the best defense is an active offense. The nature of an adequate and inclusive plan of an aggressive nature by medicine itself has not yet been formulated, and it may not be necessary or even possible for it to take the form of a definite unified plan of action. It is essential that we shall keep uppermost in our purposes the careful preservation of our position as medical advisor and as supervisor of the whole of medicine, no matter how broad the conception of the medical field may be."

When Vitality is Low

Demineralization causes many cases of cachexia, debility, undernutrition, neurasthenia, anemia and other run-down conditions. Remineralization is the remedy.

The ingredients of Fellows' Syrup are sodium, potassium, calcium, iron and manganese, together with phosphorus, quinine and strychnine.

MEDICAL PROBLEMS IN OKLAHOMA

The June issue of the Journal of the Oklahoma State Medical Association contains the President's address before the thirty-ninth annual session of the Oklahoma State Medical Association on May 12. The address was given by Dr. Henry C. Weber, who discussed some of the concrete problems of the medical profession of the State. After discussing the subjects of medical teaching and the care of crippled children, the President said:

"I think we should have a radical change in our method of handling the health department of our State. And in this statement I do not want to criticize our present health commissioner, who I think is doing everything possible to do for the State under the existing laws and practices. But we have in our Constitution a provision for a State Board of Health to be appointed by the Governor; but this has never been vitalized by the legislature, and the health department has become a political institution to be turned completely over with each incoming administration. I think the legislature should be asked to pass a law vitalizing that provision in the Constitution, so that the department may be taken out of politics and that a competent commissioner, thoroughly trained and qualified by experience to discharge the duties of this office and allowing him to remain in this position permanently, unless removed for cause. This would allow him time to organize each county health unit and would result in great good to the entire State in matters of public health and sanitation."

Concerning the care of victims of automobile accidents, Doctor Weber says:

"A serious automobile accident happens and a femur is fractured, perhaps compounded; the patient is rushed to the hospital and doctors called, *x*-rays are made and the necessary treatment given and the patient placed in bed where he must remain for several weeks. Now in 75% of the cases the patient is not financially responsible; but he gets the same care as he would if he were a millionaire. He leaves the hospital and sues the party responsible for the accident and gets a settlement and leaves. The doctors and hospitals never receive one cent for all their care as well as for the expense in caring for him.

"I think we should ask the legislature to enact some law that would protect us as the lawyers are protected. Or such as some states now have, Massachusetts for example, requiring any person who has an automobile to carry a certain amount of insurance which he receives from the state, and should be included in his payment of a license; or to pass a law making a doctor's and hospital bill a lien on any insurance or judgment he may receive, so that a claim may be filed, and the amount of the bill be deducted from his judgment and paid direct to the doctor."

(*Continued on page 859—Adv. xvii*)

(*Continued from page 858—adv. xvi*)

The certification of specialists is also discussed by Doctor Weber, who approves the Denmark plan, as follows:

"There is a general belief that any one putting himself up as a specialist in any one line should have had a minimum amount of training in that line before he can call himself a specialist. Many European countries have some such requirements Denmark seems to have the best plan, which is as follows: At the annual meeting of the medical association, a specialist committee is elected which consists of a member of the faculty of the University; a practicing specialist; a chief physician for a hospital; and a practicing physician from the country. Each member serves three years, and they work out the course of training for each specialty in consultations with the association of specialists in each field. The application for a specialist is made to the committee, and they must pass favorably upon it before any member may advertise as a specialist. This would protect the public from physicians who have become specialists overnight, and would also protect the physician who has spent much time and money to prepare himself to do special work, and he should be protected."

CRIPPLED CHILDREN IN OKLAHOMA

Oklahoma is justified in its pride in its care of crippled children described in the following report of the Committee of the State Medical Association, printed in the June issue of the Journal:

"The report of the work that has been done in the past year in connection with crippled children can best be presented by abstracting the findings as reported by the Secretary of the Oklahoma Society for Crippled Children. Considering the cause of orthopedic defects in children, the following general headings cover practically all the cases:

"1	Infantile paralysis	1147
2	Spastic paralysis	724
3.	Congenital defects of which club feet and harelip or cleft palate, or both, constitute a great majority	791
4.	Bone tuberculosis	198
5.	Osteomyelitis	235
6.	Arthritis	149
7.	Traumatic defects	328
8.	Miscellaneous which includes deformities of rickets, rare bone and muscle abnormalities, and tumors	225
	Total	3797

"It has been our experience that we are able to help a majority of the orthopedic cases that have been admitted. Some of the cases are very favorable for correction, providing that the diagnosis

ployed. There are also three such organizations without the State that are selling these contracts within Oklahoma through their fiscal representatives, one in Kansas, two in Arkansas.

"Inquiry has been made of both the American Medical Association and the American College of Surgeons as to their opinion concerning this practice. Both have condemned it as being contrary to the ethics of the American Medical Association.

"The question further arises as to whether or not there is any breaking of the Medical Practice Act of the State of Oklahoma in the actions of any of these individuals or corporations. Various angles of the question are being drawn up and submitted to the Attorney General through the State Board of Medical Examiners for an opinion."

HOUSE OF DELEGATES OF LOUISIANA

The form of organization of the House of Delegates of the Louisiana State Medical Society is similar to that in New York, and is commended by Dr. L. S. Lippincott, the fraternal delegate from the Mississippi State Association in the following report printed in the June number of the *New Orleans Medical and Surgical Journal:*

"Our Louisiana neighbors have a way of conducting the meetings of their House of Delegates which is a distinct improvement on our own method. The House meets on the day preceding the first day of scientific sessions and has the whole day to devote to business without interruption. During that day, practically all of the business of the Society is completed and no further meetings are required or held until the last day, when a short session completes the work. It might not be practical for us to devote a whole day to the meeting of our House of Delegates, but it might be possible to devote all of the first forenoon to business, thus avoiding the rush that sometimes occurs and the necessity of further sessions until the last day. It would probably insure better attendance of delegates.

"Further, in Louisiana, as with the American Medical Association, the House of Delegates is presided over by a speaker who is elected by the delegates and is usually re-elected from year to year over a considerable period. This custom relieves the President of the Society, who is otherwise always busy and may not always be best fitted for conducting a business session with dispatch and order. It also allows for the choice of a trained parliamentarian as speaker, who by re-election and service year after year learns all the 'ropes' and is able to make the House his business in the Association.

INTERNE MEMBERSHIP IN LOUISIANA

The May issue of the New Orleans Medical and Surgical Journal, the organ of the Louisiana State Medical Society, contains the following item taken from an address of Dr. C. G. Cole, retiring president of the Orleans Parish Medical Society (City of New Orleans):

"Our Board has made a concerted effort to have the State Society dues of seven dollars ($7.00) abolished, so far as Interne members are concerned, and have requested the Louisiana State Medical Society to give this proposal their earnest and favorable consideration. We feel that it is unfair to our Internes to require them to pay these dues, thereby making it prohibitive for them to avail themselves of the facilities offered by our local Society, where dues for internes are only one dollar ($1.00) per year. It is an appalling fact that out of over one hundred and thirty (130) Internes in this city only one interne is a member of our local and State Society."

The transactions of the House of Delegates of the State Society state that provision was made for interne membership.

BIRTH CONTROL IN RHODE ISLAND

The May number of the *Rhode Island Medical Journal* contains the following editorial on birth control from a Rhode Island point of view:

"The recent meeting in Providence sponsored by the American Birth Control League, and patronized by a distinguished group of intelligent, educated and altruistic citizens, both men and women, is an interesting evidence of the extension of this movement, which is gaining by leaps and bounds throughout the United States.

"That contraception is practiced among large numbers of intelligent people is no secret, especially to members of the medical profession. That the haphazard and unscientific attempts at this practice are ill advised and dangerous, and often defeat their own purpose is equa of parent.

"Accepting the fact that the public wi tinue contraception, it would seem that the liberal medical profession should welcon

MEDICAL SOCIETY ORGANIZATI IN MISSISSIPPI

The June number of the *New Orleans M cal and Surgical Journal* contains the preside address of Dr. E. F. Howard, on May 12, he the sixty-fourth annual session of the Mississ State Medical Association in which he discu

(*Continued on page 867—adv. xxv*)

(*Continued from page 866—adv. xxiv*)

the County and District Societies in a frank, intimate way.

Doctor Howard first discussed medical legislation as follows:

"Our laws regulating and safeguarding the practice of medicine did not come by chance, nor were they the gift of some inspired, lay legislator. Organized medicine brought them into existence at the cost of a great deal of time, thought, effort and money; and organized medicine alone can keep them on the statute books. The bigger and stronger we are, the better we can perform this duty."

"Last year a bill was introduced in the Massachusetts legislature that 'would have created a department of public medicine, to furnish to all citizens, without cost to them, complete medical service in all cases of sickness, accident and childbirth, including transportation to and from a hospital, maintenance in a hospital and all drugs, appliances and artificial limbs required.' (A.M.A. Bulletin, Oct. 1930). Rather comprehensive, was it not? Perhaps not without merit. But couple this with the amendments to our own practice act proposed at the last session of the Mississippi Legislature, and picture to yourself the state of affairs that will exist if such suggestions ever become laws."

Doctor Howard then described the organization of the components of the State Society in Districts and Counties and called attention to the laxity of the District Councilors in advising and inspiring the County Societies. He continues:

"Gentlemen of the Association: These matters are entirely in your hands. If you are satisfied with present conditions, turn over and go back to sleep; but if you want a real Association, an organization that will justify the proud pronouncement of the second article of the Constitution, you must wake up and see to it that these councilors and delegates get on the job. And if we are to have the success to which we are entitled, we must give some attention to the affairs of the component societies."

President Howard ends his address with a diagnosis of the conditions, but he wisely concludes:

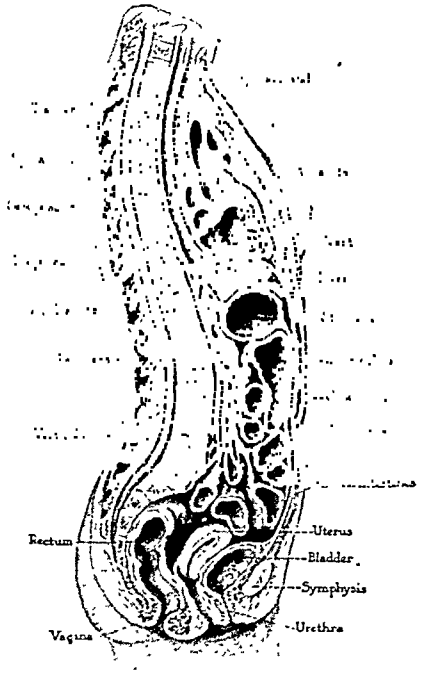
The idea is submitted for your consideration."

POLICY OF THE STATE JOURNAL OF MINNESOTA



The May number of *Minnesota Medicine,* the organ of the Minnesota State Medical Association, contains the following statement of its policy, which is about the same as that of the other State Journals:

"The main function of a state journal and Minnesota Medicine in particular should be to make physicians better physicians. If we can share in accomplishing this objective, the existence of the journal is justified. To accomplish that end, we attempt to publish articles of scientific value. Our advertisements are selected from the same viewpoint. We believe that if physicians do their job well, they hav little to fear from encroachments on the par of the cultists and irregulars.

"The subject of medical economics is not new. Individual physicians have always been concerned with economic problems of one kind or another and always will. Individually and collectively we are and should be interested in the various economic trends affecting medical practice. One of the functions of a state journal is to give expression to views on the various phases of the subject. No article has ever been barred from our pages because it dealt with an economic phase of medicine. A perusal of back numbers of the journal will show that economic subjects are by no means conspicuous by their absence. Contributions on this phase of practice are welcomed.

"It is our hope, however, that Minnesota Medicine will never allow medical economics to outweigh the scientific side of practice in its pages. When a physician becomes more interested in financial returns than in scientific attainment, he has lost in his professional ideals. So with a professional journal."

EDITORIAL POLICY IN WEST VIRGINIA

It has been the editorial policy of the NEW ORK STATE JOURNAL OF MEDICINE that derogatory criticisms shall be avoided in both the itorial and the news departments. Some her state journals do not hesitate to indulge criticism that is almost personal, as is own in the quotation from *Colorado Medicine* page 672 of the New York State Journal of ay fifteenth. However, the policy of the *West rginia Medical Journal* is similar to that of the ew York Journal, judging from the following itorial in the April issue of the West Virginia urnal:

"The Journal has found it bad policy to ake editorial comment on objectionable legslation. This publication has acquired a rather ide circulation throughout the state and its ibscription list is no longer confined strictly the medical profession. Consequently, it ocasionally falls into hands that are not exactly iendly toward the membership of the West irginia State Medical Association. On sevral occasions in the past, extracts from the ournal have been distorted and used in legislative propaganda aimed to break down our state medical practice act. Fortunately, such efforts have not been successful, but the Journal still thinks it unwise to make any statements here that might be twisted into a weapon and used by those, innocently or otherwise, who hover on the outer rim of medical practice. It should be sufficient to say that more than a dozen bills were dumped into the legislative hopper to lower the standards for the practice of medicine in West Virginia. The fact that not one of these bills was passed by either the senate or the house is a good indication that the ethical doctors of this state are held in high esteem by the two legislative bodies.

"The position of the Association and the Journal on all matters pertaining to medical legislation can be stated in quite simple terms. We stand for any and all measures that seek to improve the field of scientific medicine. We stand against any and all measures that seek to break down or to lower the standards that have been built up through sixty years of experience."

WANTED: SALARIED APPOINTMENTS EVERYWHERE for Class A Physicians. Let us put you in touch with investigated candidates for your opening. No charge to employers. Established 1896. AZNOE SERVICE is National, Superior. AZNOE'S NATIONAL PHYSICIANS' EXCHANGE, 30 North Michigan, Chicago.

For Sale—Large selection desks, chairs, tables, files, upholstered leather sets, bookcases, storage cabinets, card indices, lamps, suitable professional offices. New and used. Driver Desk Company, 6 East 33d. BOgardus 4-1952 or 5054.

MT. VERNON, N. Y.—Sale or rent, doctor's offices and residence; good location twenty-five years; splendid opportunity doctor or dentist. Apply J. H. Tallman, M. D., 171 Park Ave., Mt. Vernon, N. Y.

IMPORTANT ANNOUNCEMENT

You will be interested to know that recently a very definite IMPROVEMENT has been made in Dewey's Dew-Tone Tonics.

This improvement tends to perpetuate the character of these Tonics for which they have always been known.

At this time of the year many people experience a languor that is ordinarily called "spring-fever," which is a reaction of the system following the winter months. Dew-Tone Tonics constitute a palatable preparation suited to those suffering from fatigue. If your natural buoyancy fails, the best remedial agent is a well chosen tonic. —See front cover—*Adv.*

THE VALUE OF RESEARCH

Modern medicine demands comprehensive facilities which are afforded only by extensive experimentation, a wide range of talent, a mass of experience accumulated from thousands of clinical tests. Scientific progress has brought new concepts in the treatment of disease; has given the medical profession a long list of products that bring relief from pain, promote comfort, and alleviate distress.

The value of research in industry has made itself felt in the many lines. It is exemplified in the medical field through the offering of Eli Lilly and and Company, who were privileged to co-operate with the University of Toronto and to make available the first commercial Insulin in the United States; who synthesized and investigated a barbituric acid derivative marketed under the name of Amytal; who, through cooperation with the Harvard medical group, marketed a specific for pernicious anemia known as Liver Extract No. 343; who were pioneers in the quantity production of ephedrine products; and who after long clinical trial, presented Pulvules Sodium Amytal to the medical profession for the preanesthetic preparation of surgical cases.

Few names connected with commercial organizations command greater respect among physicians than does the name Lilly, which identifies an institution in which will be found the closest affiliation of research with practice and the finest examples of the economic service of science.—See page xii—*adv.*

VICHY CELESTINES

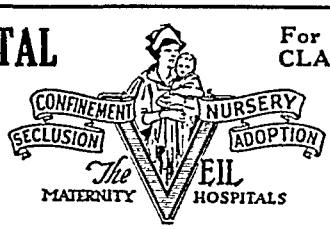
The Medical Profession will be interested to know that the Vichy Company of Paris has given special consideration to the needs of the individual physician, wherever located, in obtaining supplies of Vichy water for himself and his patients.

In order to facilitate the distribution in this country, the American Agency of French Vichy, Inc., 503 Fifth Avenue, New York, has been appointed Sole Agents for the United States.

The Vichy Company of Paris has expended large sums on improvements recently completed, at the bottling establishment at Vichy, whence the famed natural mineral water from Celestins Spring and also from the Grande-Grille and Hospital Springs is shipped to all parts of the globe.

Many American doctors have visited Vichy in France and have been impressed by the fact that patients, while taking the cure at the baths and the springs, can while away the time enjoyably at golf, tennis and other sports and enjoy the unexcelled attractions of the Casino and the beautiful Opera House—See page xxvii—*adv.*

ANTIPHLOGISTINE



Many of the periodicals issued by pharmaceutical houses are mines of information, historical and cultural, as well as scientific.

The Bloodless Phlebotomist. Vol. VII, No. VI,—the organ of the Denver Chemical Manufacturing Company, Inc., is of unusual interest. Not only does it dwell on the uses of the company's product, antiphlogistine, but it devotes five pages to an illustrated article on "Anatomy in the Middle Ages," and two pages to reproductions of the famous cartoons as, a god, an angel, a man, and Satan, according to the stage of the illness of the patient." See page ii—*Adv.*

The VEIL MATERNITY HOSPITAL

WEST CHESTER, PENNA.
Former address, Langhorne, Pa.

Strictly Private. Absolutely Ethical. Patients accepted at any time during gestation. Open to Regular Practitioners. Early entrance advisable.

For Care and Protection of the BETTER CLASS UNFORTUNATE YOUNG WOMEN

Adoption of babies when arranged for. Rates reasonable. Located on the Interurban and Penna. R. R. and the Lincoln Highway. Twenty miles southwest of Philadelphia.

Write for booklet
THE VEIL
WEST CHESTER, PENNA.

Aurora Health Institute

Mendham Road, MORRISTOWN, NEW JERSEY

Beautiful country; elevation 700 feet; only one hour from New York. Open all year. Diet, electrotherapy and hydro-therapy. Personal medical supervision. Suitable for convalescence, compensated heart lesions, hypertension, rheumatism, diabetes, anemia, etc. Homelike atmosphere. No bed-ridden contagious or mental cases.

ROBERT SCHULMAN, M.D., Medical Director
Telephone—MORRISTOWN 3260

THE ENDOCRINE GLANDS IN RELATION TO GYNECOLOGY; A REVIEW*

By LYNN LYLE FULKERSON, M.D., F.A.C.S., NEW YORK

KNOWLEDGE of the glands of internal secretion has increased with great rapidity during the past few years due to the efforts of many anatomists, biochemists and physiologists working in the laboratories of the universities, medical foundations, and commercial houses both here and abroad.

This knowledge is as yet far in advance of its clinical application. It has however, brought to the physician certain diagnostic and therapeutic uses with many others in prospect.

The activities of the various glands and the hormones that have been isolated from them are discussed in the literature chiefly by scientists with little or no clinical experience or a bias because of personal experimental work. It is after all the practicing physician who impartially decides the merit of all medical knowledge and the method of its application to the patient.

The purpose of this paper is to summarize the apparently proven facts concerning the different glands and hormones and give a clinician's view of their availability in the estimation of the constitution of women and variations from normal physiological processes as well as in correcting defects found.

According to Gudernatsch[1] the glands of internal secretion have certain physiological and histological features in common and their method of functioning appears the same, that is, through the production of a chemical substance or hormone which passes into the bloodstream and reaches a functionally associated organ and excites it to activity of a particular character.

Some of the glands if not all have definite chemical relationships to each other so that physiologically they form a system of interdependent units.

During the process of development, growth and differentiation the well regulated interaction of these glands brings about the formation of the normal organism.

"What regulates the endocrine glands?", is a question that cannot be answered. All of them must be considered as constituting an entity. Stockard[2] of Cornell University thinks that each individual inherits a peculiar endocrine make-up which cannot be altered but can be influenced.

The cerebrospinal axis, the automatic nervous system and the endocrine system function harmoniously together under normal conditions and but for external stimuli would doubtless maintain the balance and interrelationship inherited. The psyche affects the endocrine system, both the sympathetic autonomic and the vagal or antagonistic autonomic, which are closely related embryologically, influence it, the vitamins, which are of equal importance with the hormones modify it.

The most important glands concerned in female sex physiology are the pituitary, thyroid, adrenal and ovary, although the mammae must also be considered.

The Pituitary Gland. The pituitary gland has been shown to be of first importance in the gynecological field through its complete control of the ovary. It consists of four parts, the anterior lobe, the intermediate lobe, the posterior lobe and the pars tuberalis. The hypothalamus and the pituitary gland function dependently together. The anterior lobe appears to be the only portion that is essential to life. It yields four hormones or at least has four distinct activities. One, that of Evans and Long[3] of the University of California, stimulates growth and its deficiency results in infantilism. The second and third affect the ovary. The fourth influences pregnancy hypertrophy of the breasts and lactation according to Corner[4] or is metabolic or perhaps constitutes a fifth in Zondek's[5] diagram. Chiefly through the work of Phillip Smith[6] of Columbia University, Evans and Simpson,[7] and Aschem[8] and Zondek[9] the physiology of menstruation ovulation, impregnation and parturition has been found to be regulated by the influence of two of the four hormones of the anterior lobe of the pituitary.

Zondek terms one (prolan A) the follicle-rip-

*Read before the Broome County Medical Society, Binghamton, N. Y. April 7, 1931.

ening (Follikelreifungshormon) or ovulation hormone and the second (prolan B) the lutein-forming (Luteinisierungshormon) or luteinization hormone[10]. The former causes the development of a Graffian follicle in the ovary and the consequent and subsequent production of the follicle hormone or estrin as named by A. S. Parkes.[11]

Estrin produces growth of the uterine musculature with swelling of the endometrium and proliferation of its basal layers.[12]

The second anterior pituitary hormone causes the ruptured Graffian follicle to be transformed into the corpus luteum producing the lutein cells and the elaboration of two other hormones. That of Corner[13] of Rochester University produces the endometrial thickening characteristic of the premenstrual phase of menstruation or the formation of decidua if impregnation occurs and has been called by him progestin.

The second corpus luteum hormone, that of Hisaw[14] of the University of Wisconsin, produces relaxation of the pelvic ligaments in the guinea-pig with mobilization of the pubic bones. The name relaxin has been given to this hormone. It does not produce pregestational changes in the endometrium.

Zondek[15] summarizes a recent article as follows: "Ohne Hypophysenvorderlappen, ohne Vorderlappenhormone keine Sexualtätigkeit, keine Eireifung, kein Sexualrythmus! Ohne Vorderlappen Atrophie der Sexualorgane! Ohne Vorderlappen keine Konzeption! Bei Zerstörung des Vorderlappens Tod des befruchteten Eies!"

This may be translated, "Without the anterior pituitary lobe, without the anterior pituitary hormones no sexual activity, no maturation of the ovum, no sexual rhythm! Without the anterior pituitary lobe atrophy of the sexual organs! Without the anterior pituitary lobe no conception! With destruction of the anterior pituitary lobe death of the fertilized ovum!"

Kamm[16] and his co-workers have demonstrated that the pituitrin of the posterior lobe includes two hormones, alpha-hypophamine (oxytocin) which produces contraction of smooth muscle and beta-hypophamine (vasopressin) which has a pressor and a diuretic and antidiuretic action[17].

The posterior lobe controls sugar and water metabolism.

The hypothalamus rather than the pituitary has been shown by Smith[18] to regulate fat metabolism and its disturbance to cause obesity.

The Ovary: Three separate hormones have been found in the ovary but the action of only two is understood. Estrin is secretive in the follicle under the influence of prolan A, or the alpha hormone of the anterior pituitary gland. Progestin is secreted by the lutein cells of the corpus luteum because of the influence of prolan B, or the beta hormone, although the lutein tissue itself originates through the action of prolan A. Estrin produces the development of the endometrium which characterizes the interval phase of menstruation. It collaborates with progestin in producing the endometrium of the premenstrual phase. Menstruation results from degeneration of the corpus luteum through withdrawal of prolan B. If the ovum becomes fertilized the trophoblast cells are thought to form a hormone which stimulates the anterior pituitary gland to produce more prolan B, so that the corpus luteum goes on developing and the endometrium continues to grow under the continued influence of progestin. Labor results from failure of the trophoblast hormone.

The Suprarenal Glands: The suprarenal glands consist of two embryologically independent parts, the cortex which is derived from the mesoderm and the medulla which is derived from the ectoderm. The cortex is indispensable to human life. Recently Swingle[19] and Pfiffner of Princeton University and Hartman,[20] Brownell and Hartman of Buffalo University have prepared an extract or cortical hormone named by them cortin which will prolong the life of adrenalectomized animals indefinitely and has revived a moribund patient with Addison's disease.[21] It is given subcutaneously or intravenously in doses of 10 to 20 c.c. daily.[22] The isolation of epinephrin from the adrenal medulla by Takamine was an achievement the clinical importance of which is generally recognized. It is one of the three hormones the chemical composition of which is known. The other two are thyroxin from the thyroid gland and estrin from the ovary.[23]

The adrenal glands are not only essential to life but seem to be growth stimulating. The cortex appears to collaborate with the anterior pituitary in the development of the sex organs.

The medulla synchronizes with the pressor activity of the posterior pituitary. Both acting upon as well as in response to the influence of the vegetative nervous system, the medulla serves the individual in meeting emergencies.

Adrenalin reduces the coagulation time of the blood, increases the pulse rate and respiration, raises the blood pressure, increases the blood sugar, the blood lactic acid and basal metabolism.

With inadequate adrenals there is found a small cardiovascular system, low blood pressure, low blood sugar, prolonged coagulation time, and undeveloped genitals.[24]

The Mammary Glands: Corner[25] has recently shown that the proliferation of the mammary glands seen in pregnancy and lactation after parturition are the result of pituitary hormones.[26] He believes that the mammary glands must be first brought to full pubertal condition by the influence of estrin (ovarian follicle hormone) and finds that the luteal hormones are not necesary.

As yet no internal secretion has been isolated but it is likely that one or more exist as Can-

dela[27] has pointed out that injections of mammary extract may suppress estrus or change its rhythm, may produce atrophy of the ovaries and genital tract, may cause hypertrophy of the thyroid, breast, adrenals and the pituitary, increase weight and bring about sterility

The Thyroid· The function of the thyroid gland is to regulate metabolism De Quervain[28] ascribes to it the control and stimulation of tissue growth in general, control and stimulation of the functional processes of tissues, neutralization of toxic substances produced in the normal metabolism of the tissues and assistance in the defensive action of the organism against bacterial toxins

Specifically it controls oxidation, pulse rate and pressure, blood sugar, body temperature, brain and nervous system activity Through its vagus effect it regulates peristalsis perspiration and the flow of gastric juice.

Thyroxin, the hormone isolated from it possesses most of the activities of the whole gland One other hormone with no discoverable influence has been recognized and there is thought to be a third [29]

Abnormal Function Many instances of abnormal functioning of the glands of internal secretion are observed There may be an insufficiency of production of hormones because of hypoplastic, diseased or inhibited gland tissue, when the condition may be termed one of hypofunction, or there may be an overproduction of hormones because of overgrowth, new growths, diseases or over-stimulated gland cells, when the term hyperfunction best describes the condition, and again there may be a lack of balance between the several hormones elaborated in a gland, so that the term dysfunction or imbalance best describes the state of that gland

It is seldom that the physician can attribute the clinical picture to disturbance of a single gland for usually several are at fault

Furthermore, disturbance of function of the endocrine glands is only a part of a complicated functional derangement of the entire organism Neuroses are frequent Gastro intestinal derangements are usual The blood making organs are often defective, with resulting secondary anemia

Endocrine disturbance[30] of function may effect the generative organs by producing amenorrhea, oligomenorrhea, menorrhagia, metrorrhagia, dysmenorrhea or sterility

All these factors must be taken into consideration in explaining the menstrual disorders the hypoplasias and sterility

It is best to classify the clinical pictures according to the effects produced by insufficiency, overfunction or dysfunction of each particular gland

Abnormal Pituitary Function Following labor or abortion there is frequently observed a type of young woman who becomes obese, sometimes gaining a hundred pounds or more within a very short time After a period of amenorrhea of months or years she presents herself for examination She is found to have hyperinvolution of all the genital organs so that in some instances they resemble the infantile While the obesity is the result of disturbance of the hypothalamus, the genital hypoplasia results from anterior pituitary influence

These young women have oligomenorrhea or amenorrhea and with disappearance of the sex cycle, also sterility Enormous breasts are often present and since many times a history of a prolonged period of lactation is given the genital hypoplasia was formally termed lactation atrophy

This clinical syndrome is similar to that produced by Cushing[31] in female dogs by partial ablation of the anterior pituitary The experimental animals became obese the generative organs became hypoplastic and the sex cycle disappeared

The cause therefore seems to be an anterior pituitary deficiency

The even distribution of fat leads the clinician to suspect thyroid hypofunction rather than pituitary but the basal metabolism test fails to confirm the opinion since the rate is usually within the normal range

At puberty two types presumably due to pituitary insufficiency are observed One type is obese and resembles the postpartal picture just described The second type is that of the adiposogenital dystrophy of Frohlich

This girl is often tall and with long arms and legs She has delicate fingers, breasts enlarged to a disfiguring degree, a slender waist sometimes though not always she has marked fat deposits on shoulders abdomen, buttocks, and hips

Both puberty types have hypoplastic genitals and menstruate late, scantily, infrequently or not at all

Hyperfunction of the anterior lobe of the pituitary produces giantism or precocious genital organs and sex cycle before puberty and acromegaly if it develops after maturity

Abnormal Thyroid Function Thyroid hyperfunction may be accompanied by menorrhagia or oligomenorrhea or amenorrhea Excessive menstrual bleeding is seen more often

In my experience amenorrhea or scanty menstruation are more characteristic of thyroid hypofunction Menorrhagia is observed, however, in certain cases of hypothyroidism in which hyperplastic endometrium is obtained by curettage Here the hemorrhage is due to a persistence of the estrin effect as in puberty or climacteric bleeding although the thyroid is the primary cause [32]

Either hypothyroidism or hyperthyroidism are apt to produce sterility The influence upon the

ovary here is not clear. It may be through associated disturbance of the anterior pituitary and consequent failure of the pituitary hormones to activate the ovary in the normal elaboration of estrin and progestin.

Abnormal Ovarian Function: Hypofunction of the ovaries is observed in the amenorrheas following constitutional diseases and secondary anemias, also in dietary defects and accompanying disturbance of other endocrine glands.

Amenorrhea alternating with menorrhagia and metrorrhagia of ovarian origin may result from interference with function or disturbance of balance between the estrin of the follicle and the progestin of the corpus luteum. This clinical picture is often seen in women with retention cysts.[33]

Puberty bleeding[34] and the bleeding at the climacteric are apparently due to an ovarian deficiency. An absence of corpora lutea and a persistence of the Graffian follicle are reported by Novak[35] of Johns Hopkins University and others. The diagnosis of this condition is made by finding the characteristic Swiss-cheese pattern of the glands in the endometrium removed by curettage. The cause appears to be a continuance of the estrin effect without progestin activity since no corpora lutea are found in the ovary.

Abnormal Adrenal Function: Hypofunction of the adrenal glands, as observed in girls at puberty with Addison's disease, causes lack of genital development and failure of menstruation to appear. In adult women amenorrhea is often the earliest symptom of Addison's disease to be noted.

Hyperfunction in childhood is thought to produce precocious sexual development; in adult life it creates hypertrophy of the ovaries and exaggeration of the secondary sex characteristics.

Diagnosis: A complete physical examination of the patient including blood pressure is presupposed. Special note is made of the thyroid, the breasts, the distribution of fat and its amount in proportion to the stature of the patient, the degree of development of the generative organs, especially the uterus and ovaries.

If endocrine imbalance is suspected, laboratory aids are necessary. The most important is the basal metabolism test which measures thyroid activity. It is only accurate when performed by the Tissot method with outdoor air for inhalation as done by Dr. Bailey at the New York Post-Graduate Hospital and others, not room-air or oxygen. Every care should be taken to ensure that the test shows the patient's actual basal rate. The graveyards are said to be full of those operated upon because of improperly performed tests. Stander[36] of Johns Hopkins University and others have confirmed the normalcy of an increased basal rate during pregnancy. The average is quoted as high as thirty per cent above the normal non-pregnant woman in Baer's[37] series of cases.

Hemoglobin and blood morphology are important since most women with endocrine disturbance have a secondary anemia.

To appraise the pituitary, urinalysis, the blood sugar and a sugar tolerance test are required at the least and in some cases an *x*-ray study of the sella turcica.

Adrenal function is judged by hairiness, pigmentation, asthenia and the Addisonian syndrome.

Pelvic bimanual examination permits an estimation of the size and consistency of the ovaries. Retention cysts may explain a disturbed menstrual cycle, or a sterility.

Present Therapeutic Applications: These may be summarized briefly under hypoplasias, menstrual disorders, sterility and diagnostic tests.

Infantilism and Acquired Hypoplasia of the Genitals: As yet no standardized anterior pituitary hormone is available in this country although one is advertised in the German journals.

The gland substance given by mouth has little if any effect. If used at all it should be given in doses of 60 grains or more daily and the cost is prohibitive.

Ovarian substance is of little value given by mouth. Estrin given hypodermatically would entail too much expense and prolonged physical discomfort without appreciable clinical benefit.

If the basal metabolism is low, the administration of thyroid substance in indicated dosage offers most in these conditions.

Sterility: The correction of thyroid or pituitary insufficiency through weight reduction, where obesity exists; of hyperthyroidism by medical treatment or by operation; the correction of a hyporthyroidism by the use of the gland substance, or the correction of diet deficiencies, especially through the use of wheat germ with its vitamin E[38] may overcome a functional sterility.

After progestin becomes available, it may provide a method of preventing sterility and habitual abortion caused by excessive production of estrin, if such a functional cause exists, as now seems likely as judged from the work of Papanicolaou,[39] Parkes and Bellerby,[40] Corner and Allen,[41] and G. L. Kelly.[42]

Menstrual Disorders: Amenorrhea, hypomenorrhea, dysmenorrhea or menorrhagia may be corrected by the use of thyroid substance if the basal metabolism test shows its need.

Scanty and infrequent menstruation, amenorrhea and sterility all appear to be improved by reducing the weight of the obese regardless of the endocrine factor at fault. This should be done by diet where thyroid is not indicated, care being used to preserve a proper vitamin balance.

If anemia is present it requires correction. Estrin or ovarian therapy is not usually indicated since there is no advantage in forcing a woman to bleed until the cause of her disorder is removed.

Other Clinical Applications of Present Knowl-

edge The Ascheim-Zondek test is based upon the fact that a large amount of the anterior pituitary sex hormones are present in the urine during pregnancy. The concentration has been found to be approximately 10,000 mouse units per liter and begins immediately after fertilization of the ovum so that the test becomes positive as early as four days after the date of the expected menstruation

Ascheim and Zondek employ the following technique [43] Five female white mice weighing between six and eight grams and from three to four weeks old are injected with the slightly acidified morning urine of the patient in six divided doses varying respectively from 0 2, 0 25, 0 3, 0 3 to 0 4 c c The total quantity of urine injected varies from 1 2 c c in the first mouse to 2 4 c c in the fifth mouse On the first day the injections are given at 11 A M and 5 P M , on the second day at 10 A M , 2 P M , and 5 P M , on the third day at 10 A M At the end of four days, that is on the morning of the fifth day, the mice are killed and the ovaries examined with a hand lens and also by microscopic examination of serial sections blood-spots and yellow protrusions indicate pregnancy Investigating the accuracy of the test Parvey[44] found it in agreement with the clinical course in each of 191 cases This test is also positive with ectopic pregnancy, hydatidiform mole, and chorion epithelioma[45] and so becomes an important aid in recognizing these conditions

The Allen and Doisy test[46] for pregnancy is based upon the work of Stockard and Papanicolaou of Cornell University[47] and depends upon the demonstration of one mouse unit of estrin in 10 c c of a patient's urine The urine is injected into three castrated female white mice in five doses of 2 c c each over a period of two days Within forty eight hours vaginal spreads show changes characteristic of estrus If there is complete absence of leucocytes and mucus, and the smear shows only non-nucleated squamous cells or a preponderance of them, pregnancy is indicated It is a less reliable test than the Ascheim-Zondek test

The Siddall[48] test for pregnancy depends upon the effect of the anterior pituitary hormones and estrin in the blood of pregnant women, on the genital tract of immature mice and clinically is of less value than the other two tests

Clinical Applications in Prospect C F Fluhmann[12] of Stanford University has suggested a test based on the Ascheim-Zondek test for pregnancy which utilizes the blood of the patient and determines the presence of an abnormal amount of anterior pituitary hormones The test is positive in pregnancy, after castration by radiation or operation and after the menopause, also in certain women with menorrhagia and dysmenorrhea It should prove of value in determining the state of ovarian function

G L Kelly[49] of the University of Georgia has demonstrated that conception can be prevented in mature female guineapigs by the injection of a minimum dosage of 10 to 15 rat units of estrin, given immediately after copulation in divided doses of equal amounts over a six-day period Pregnancy of two weeks duration could be interrupted in practically all cases with a total dosage of 100 rat units

Animals pregnant four weeks were made to abort with a dosage of 100 to 150 rat units but with a high maternal mortality

In guineapigs pregnant 6 to 8 weeks from 300 to 1,150 rat units terminated pregnancy but resulted in the death of the mother Apparently these deaths were due to dystocia rather than to the injection of estrin

The conclusion then is that an excess of the follicle hormone (estrin) over the corpus luteum hormone (progestin) is incompatible with conception and with the continuance of normal pregnancy in the guineapig

A clinical application of this study to the problems of contraception and spontaneous and therapeutic abortion is a possibility of the future

Pharmaceutical Preparations Estrin may be obtained in ampules for hypodermatic and in some instances intravenous use, also as vaginal suppositories It is marketed by many firms under many names Doisy[23] of St Louis University and Butenandt of Gottingen both have produced a crystalline form of estrin ($C_{18}H_{23}O_2$)

Progestin is not yet available commercially in this country although a German product, "A corpus luteum hormone in oily solution," is advertised

Cortin is not yet obtainable except for experimental purposes

Several anterior pituitary extracts are to be had but as yet few are perfected so that one should use them cautiously, if at all Prolan A and prolan B are advertised as separated and standardized

Thyroid substance and thyroxin remain of widest application of all the endocrine products, although pituitrin is used extensively in obstetrics and the postoperative care of the surgical patient

ORAL DIAGNOSIS OF IMPORTANCE TO THE MEDICAL PRACTITIONER

By SAMUEL CHARLES MILLER, D D S, NEW YORK, N Y

Prepared on the Occasion of the 100th Anniversary of New York University

The inter-relationship of medicine and dentistry is rapidly becoming evident in the minds of both practitioner and patient That many systemic conditions show oral manifestations and that local oral conditions may produce general disease has been continuously demonstrated At the New York University Clinic we have been recording hundreds of cases of rheumatism, neuritis, inflammatory arthritis, iritis, etc , which were improved or entirely cleared up with the removal of teeth showing definite rarefied areas at their apices However, the other oral possibilities related to general diagnosis have not been commonly stressed and are, therefore, very often omitted even in oral examinations

The story of the physician who advised the patient to take out all his teeth and was promptly obliged by the removal of a full upper and lower denture from the patient's mouth, is a common one, although not very instructive In this mouth, in spite of the fact that teeth failed to be present, the diagnosis may still be correct Radiographic examination of these edentulous areas reveal a surprising variety of conditions that may be related to the general disturbance (Fig 1) There may be impacted or unerupted teeth which are producing referred pains or are enclosed in a cystic membrane with a hematogenous infection present It is not uncommon to find these teeth entirely denuded of enamel in spite of the fact that they have never become exposed to the oral cavity We may find retained roots which have become entirely covered by bone and mucous membrane and which give absolutely no objective indications of their presence except through careful dental radiography The most important of these hidden areas, probably because it has been least stressed, is "residual infection" The occurrence of this has been recognized and emphasized by McCall [1] It has been found by observation of numerous cases that the extraction of a tooth, is not always the solution of the problem Very often a granulomatous or cystic sac is allowed to remain and although, admittedly, the majority of these are taken care of by the body resistance, it has been shown that these areas may remain for years sometimes even increasing in size and frequently acting as foci of infection At the clinic as well as at the office we have made it a point to remove these foci of infection with most gratifying results, when the general condition and the physician's advice warranted it

When the teeth are present I again find that there are many conditions which have not been sufficiently emphasized in their relation to unilateral or bilateral neuralgia The most important of these is traumatic occlusion or an improper biting balance, a condition which has been justly emphasized to the dental profession by Dr Paul R Stillman Due to the soft and cooked food diet which is becoming more and more common in civilized countries we find that the functional activity of the teeth is reduced and the biting surfaces do not receive the necessary attrition for occlusal adjustment The form of the newly erupted teeth is no more adapted to function in middle age than is the size and strength of the rest of the juvenile body When, due to insufficient function the teeth do not mill as age progresses, changes in the tissue around the teeth are rapidly manifested (Fig 2) This condition may also be brought on by improper dental restorations which change the line of occlusion, by extractions without placement of bridges (resulting in drifting), and, quite frequently, by the eruption of the third molars in arches not large enough to accommodate them This latter produces a forward pressure on the dental arch causing crowding, and disturbing the proper occlusion of the biting surfaces When traumatic occlusion is found in the presence of trifacial pain or referred neurotic symptoms it is best to have this feature corrected immediately This can most often be adjusted by judicious grinding by the periodontist but in some cases orthodontia and even extractions are indicated This special diagnosis should be placed in the hands of the dentist as early as possible

However, what is more common is to see this disbalance of the bite as a causative factor in periodontal disorders These disturbances are instituted quite early and I believe that the physician is very often the first to see them and should be able to determine their significance The perceptible loosening of the teeth and the flow of pus which have become synonymous with "pyorrhea" are the last stages of the disease and should be avoided if ideal results for the patient's benefit are to be courted

Nature has kindly given us a number of diagnostic signs, both clinically and radiographically, which, if we can read them, warn us sufficiently early of the approach of this unpleasant clinical picture The normal gingiva should present a healthy pink appearance which changes at a definite line (about 15 millimeters from the gum margin) to a distinctly darker pink at its junction with the alveolar mucous membrane The margin of the normal gingiva comes to a knife edge and festoons smoothly and symmetrically around the teeth A blunting of this margin or an irregularity in the marginal contour may be considered the initiation of periodontal pathology The healthy gingiva is not shiny and mucous but presents, rather, an appearance of stipling A

FIGURE 1—H. S., MALE, WHITE, AGE 36.

Sixteen film radiographic exposures of mouth in which the physician suspected focal infection of dental origin. The patient was referred to a dentist who placed bridges and crowns to fill in edentulous spaces. Six months after this, because all symptoms persisted, patient was referred for radiographic diagnosis. This revealed three impacted teeth and two pulpless teeth with periapical involvement. Removal of the three impacted teeth and the two suspicious non-vital teeth was followed by immediate cessation of general symptoms.

a—Impacted teeth.
b—Non-vital teeth with periapical involvement.
c—Non-vital tooth without periapical involvement.

It will be noted that all teeth appear in at least two exposures. The advantage of this is that we see each tooth from two angles and can thus arrive at a better interpretation without the interference of anatomical landmarks.

slight thickening of the marginal gingiva producing a shiny blunt edge is often the first definite clinical sign of a periodontal disturbance due to traumatic occlusion. This morphological change has been termed the "traumatic crescent" and appears at the margin of the gingiva opposite to the point at which the stress is being applied. If the disturbing factor is allowed to remain the gum margin thickens rapidly and forms a well outlined hypertrophy, very often without noticeable color change. This is referred to as festooning and is specially designated as "McCall's festoons" in deference to the man who first called attention to this diagnostic factor. Another most important manifestation of early periodontal disease is the appearance of "Stillman's Clefts." These are breaks in the margin of the gum which appear as if the edge were cut through with a

knife. These are due to traumatic stress on the tooth and, like our previous diagnostic factors, are due to an excessive pressure at a point on the tooth opposite to the lesion. Any deviations from the normal gum contour or color distribution should be considered carefully as they are most probably indications of deeper pathology.

FIGURE 2—M. L., FEMALE, WHITE, AGE 21
Photograph shows definite destruction of the tissue on the labial of the lower right central incisor. This is due to the strain being placed on this tooth alone in the protrusive or biting position

Although the aforementioned conditions are indicative of gingival disease they are the *initial* stages of periodontoclasia and therefore are not associated with any, but local symptoms. However, they indicate the presence of traumatic occlusion and call for its elimination to avoid more serious tissue damage.

Oral manifestations of many general conditions, especially of blood changes (purpura hemorrhagica, pseudo- and true leukemia, anemias, etc.) (Fig. 3), are often the first symptoms of the disease, and are quite commonly mistaken for Vincent's Infection. Various types of exanthemata, erythemas, and herpes, as well as dietary deficiencies show oral manifestations whose association with their mother illness is frequently overlooked. Syphilis, diabetes, nephritis and tuberculosis often show pathognomonic symptoms in the oral cavity. (Fig. 4) Pneumonia, measles and whooping cough may produce effects on the gums and teeth.

Vincent's Infection, then, cannot be confused with these if a few of its symptoms are related. First and foremost is the destruction of the interproximate papillae. This is accompanied by a rise in temperature, fetid breath, metallic taste, increased salivation and sometimes enlargement of the submaxillary and cervical lymphnodes.

Of all types of Vincent's Infection, the acute responds most rapidly to treatment, although the rationale does not differ for the acute, subacute or chronic types. I believe that all chronic cases of this disease have been acute at one time and, if treated at that stage, much unnecessary discomfort and tissue loss could be avoided. Although the abundance of the spirilla and fusiform bacilli in the tissue is important, their mere presence is not indicative of Vincent's Infection (phagadenic gingivitis). It has been shown that the organism is found in healthy mouths and I have seen it commonly associated with practically all lesions of the oral cavity where there is not an open freely washed surface. Although the Vincent's infection is usually seen in the presence of a Vincent's Angina we may have either occurring without the other. Since Vincent's organisms have been recovered in atypical forms of meningitis, mastoiditis, sinusitis, etc.; it is indeed valuable for the physician to be able to diagnose and hasten the eradication of the oral conditions. Vincent's Infection occurs quite often, nowadays, in the mouths of young girls due, most probably, to the prevailing habit of cigarette smoking and the common practice of excessive dieting, both of which tend to lower the tissue resistance.

Dietary disturbances, such as scurvy and rickets, produce oral manifestations. In rickets, because of its appearance so early in life,[2] the disturbance is usually manifested in the improper

FIGURE 3—V. C., FEMALE, WHITE, AGE 15
Gingival edema and discoloration associated with Purpura Hemmoragica.

formation or calcification of the teeth. Scurvy, on the other hand, appears as a gum condition showing a bluish bloating of the gingival tissue sometimes enlarging to almost cover the crowns of the teeth. (Fig. 5) The scorbutic gingivitis is not a rarity although it is seldom seen in its severe stages without general disturbances. It is

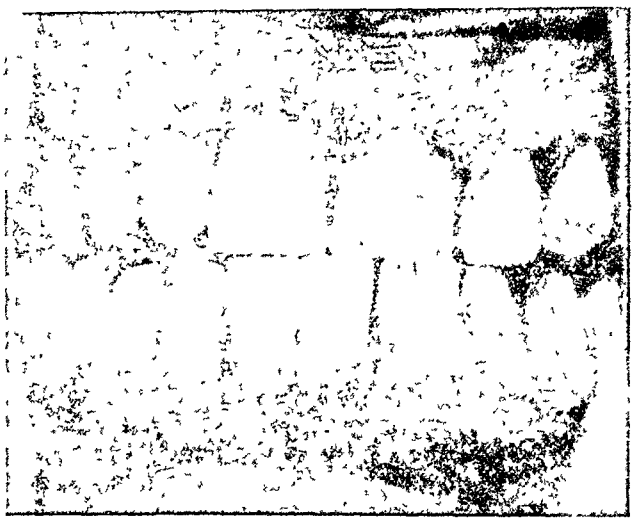

FIGURE 4—M. S., FEMALE, WHITE, AGE 15.
Gingivitis associated with diabetes. Radiograms of this case show considerable bone destruction, in spite of patient's age.

FIGURE 5—L. S., FEMALE, WHITE, AGE 43.
Scorbutic gingivitis. Note peculiar shiny appearance of tissue which is blue, bloated and easily injured.

most prevalent in New York among the Italians and Jews.

I have noted a decalcification of the teeth, most probably associated with a calcium-phosphorus disbalance, in housewives, all of whom claimed they ate whatever came to hand (which practically always turned out to be rolls or bread, and coffee). By insisting upon orange juice, milk and fresh vegetables in the diet, I have seen these arrested, although the destruction once produced, can only be repaired by artificial replacement. The patient is always referred to the physician for diet in any unusual cases, especially during childhood, pregnancy or lactation in order to avoid unpleasant sequellae of which the gingivitis and tooth dissolution are examples. It is important for the physician to impress upon the patient the value of a properly balanced vitamin-containing diet.

If this paper arouses a greater enthusiasm on the part of the physician for a closer relation between the medical and dental practitioner in the diagnosis of related conditions, I will feel amply repaid for my efforts.

AMPUTATION OF THE LEG IN DIABETES

By R. FRANKLIN CARTER, M.D., F.A.C.S., NEW YORK, N. Y.

THE essential factors for the treatment of every patient with gangrene of the lower extremity and diabetes are present to a greater or less degree. And variation in the extent of these factors should determine the course of action.

Diabetes no longer can be given the position of dictator as to the surgery to be employed. Since the advent and use of insulin the diabetes can be controlled, and surgery therefore rests upon the two remaining factors: infection, and arteriosclerosis. The extremes of diabetes, acidosis and alkalosis are still encountered, but with less danger to the patient than before the use of insulin. Infection still materially influences the administration of insulin, but even in its extremes insulin and the proper administration of glucose may be expected to maintain the patient in the safety zone. Variations in the degree of diabetes are encountered to such an extent that the surgeon who is in association with competent medical assistance may almost disregard the diabetic factor. Keeping in mind only the extremes of acidosis and alkalosis and avoiding radical procedures when either of these states exist.

The presence of gangrene may be noted long before the surgeon is called in Its cause varies no doubt, but it is most certainly influenced by both arteriosclerosis and infection To what extend the diabetes, per se, contributes is doubtful One may contend that diabetes causes arteriosclerosis which in turn causes gangrene or that arteriosclerosis has caused the diabetes, and that the gangrene and diabetes are co existent in the same individual Whatever may have been the arrangement of the primary factors infection is sure to bring the request for consultation to the surgical department

When infection occurs in the presence of diabetes, arteriosclerosis and gangrene the surgeon quite naturally is not so much concerned with the early arrangement of the essential factors as he is with the present status of the patient, and what is to be done for the control of the infection and the spread of the gangrene

Anyone faced with such a situation and forced to adopt a plan of action could justify the course selected and pursued by reference to the voluminous literature of the subject There are other factors which, in some instances, become controlling besides a real surgical analysis of the situation If one wishes to amputate immediately, the patient may refuse, and if one wishes to temporize the medical staff may frown upon that in view of the severity of the diabetes, and if one should believe that the critical nature of the patient s condition makes the employment of any surgical procedure likely to be poorly tolerated the advent of death under those circumstances may leave in his mind that doubt that too little was done Also the presence of a death after radical procedure may leave in the surgeon's mind the wish that he had at least temporized or waited for the infection to subside The situation is trying because of its severity and lack of clear cut indices to the essential factors

Study of the essential factors by animal experimentation is difficult, and it has not been properly carried out To disassociate these factors and observe them is comparatively simple, but to combine them is much more difficult and only in combination can they be accurately judged as to the part they properly play

The extent, rapidity of increase, and duration of the gangrene can be accurately determined This, however, is of importance only in the absence of infection And the presence of gangrene without infection is unusual Dry gangrene is common, but this term does not indicate the absence of infection, merely the absence of putrefactive bacteria or sloughing

Arteriosclerosis may be assumed to be present in all patients of middle age or more And it is in such patients that gangrene is usually encountered Absence of pulsation in the dorsalis pedis and popliteal arteries is usually present However, the nature of the surgery to be employed cannot be determined by this physical sign

Infection, its duration, its extent, its cause of general reaction, its location, and its rapidity of increase after all should determine the immediate surgical procedure more than any other single factor While infection should receive major attention the other factors for consideration should not be overlooked But in any given patient the first determination of the surgeon should be based upon the infection and the surgical procedure to be employed likewise

An assertion that all infection of a virulent nature located in the soft tissues of the lower extremity should become localized before amputation of the extremity is the result of experience in these patients with both conservative and radical treatment During this experience insulin only has been of a material change

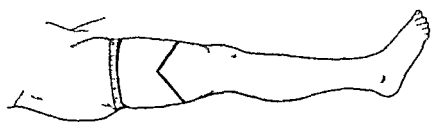

FIGURE 1

Shows the leg prepared for amputation, tourniquet applied and the line of incision made The incision extends directly through skin fascia and muscle in the direction of the bone Care is exercised in making the incision in avoiding retracting the skin or fascia away from the underlying layers

In the presence of a well developed infection of a gangrenous area in the lower extremity of a patient with diabetes amputation at the thigh will carry an unnecessarily high mortality And palliative surgical treatment by amputation of all the gangrenous and actively infected area will materially lower the mortality This procedure should be carried out without regard for the future function of the extremity The line of amputation should be carried back on the foot to an area in which thrombosis of the vessels does not exist and no flaps or undermining of the skin area should exist Cutting the area away as one would cut off portions of an apple, to reach the limit of thrombosis of vessels should be carried back on both the dorsum and plantar surface of the foot with the amputation of all the gangrenous toes back to the metatarsal head The shaft of the metatarsal bone should not be

opened but allowed to sequestrate in the event that further amputation is not required.

Elevation of the extremity and copious wet dressing should be employed during the few days interval in which the progress of the infection is to be determined. Should the infection subside, the gangrene fail to reappear and the diabetes be kept under control with the appearance of active healing of the open surfaces recovery with saving of the extremity may be looked for. However, reappearance of the gangrene may necessitate amputation of another toe or a portion of either surface of the foot.

The death of those portions of the foot that ordinarily receive the least blood supply is noticeable, viz., the fascia and tendons. If the fascia of the sole of the foot dies up to and in-

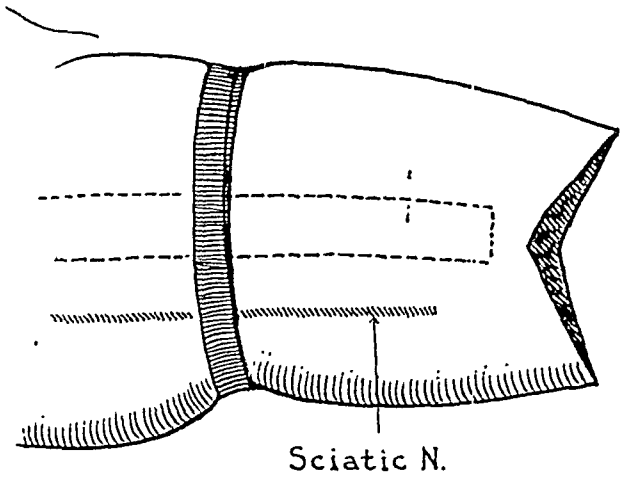

FIGURE 2

Shows the incision completed, vessels ligated, the soft tissues have been stripped back from the bone, the bone amputated, the nerve pulled down and amputated as high as possible. Then the soft tissues are allowed to fall into place over the bone end.

cluding the heel necessitating removal of all of the skin of the plantar surface of the foot, amputation above the knee is indicated. If the shaft of a metatarsal bone becomes infected, amputation is indicated. But only when there are no constitutional signs of infection as evidenced by temperature and lymphangitis. Wide exposure of the underlying dead fascia and wide drainage of an infected area of bone should precede amputation, if there are constitutional symptoms of infection.

The site of operation that is best suited for patients in this group does not vary. It should invaribly be above the knee. However, the type of operation is not so generally agreed upon and variations that include all methods between the simple guillotine and especially contrived flaps for covering the stump have been advocated.

In an experience which includes the use of various types of operation one is impressed by the results derived from the simple procedure

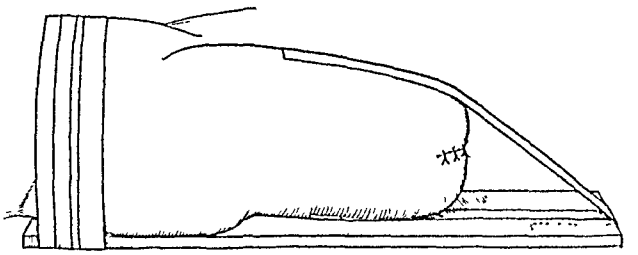

FIGURE 3

Enough gauze is placed over the cut surface to prevent infection, then adhesive strapping is begun above the line of incision, anteriorly, laterally, and posteriorly to make traction downward and thereby overcome the retraction of the muscles. A splint made as wide as the stump and long enough to extend from the crest of the ilium to ten inches beyond the stump is anchored by the weight of the pelvis to which it is strapped with adhesive. The lower end of the splint receives the pull from the adhesive exerting extension on the stump. Over all the strapping of the stump a liberal dressing of cotton is then applied with a loose circular bandage. And the first dressing should not be done for eight to twelve days unless there should be evidence of infection, viz., temperature elevation after the third day or severe pain and temperature. After the first dressing the splint and traction may be discontinued.

of a V-shaped incision with high amputation of the bone and closure of the skin edges only. In the evolution of the present method employed skin fascia flaps were first used to insure a good covering for the bone. Sloughing of the flaps resulted in an abandonment of this method. Following that the muscles were sutured over the bone, then the fascia, then the skin and retaining sutures of silkworn gut were placed through all layers. The fascia sloughed. Then the fascia only beneath the skin was sutured and still there were fascia sloughs. And then the skin and fascia only were closed over the bone with interrupted sutures of silkworm gut. Still there were sloughs which always seemed to be principally fascial. Finally the skin surfaces only were closed with interrupted sutures. And with high amputation of the bone, that is, fully three inches above the skin margin, and traction to resist the contraction of the stump soft tissues, sloughing has not been encountered and the final stump results in a much more ample covering for the bone end.

THE ADMINISTRATION OF QUININE HYDROCHLORIDE IN MULTIPLE SCLEROSIS*

By RICHARD M BRICKNER, M D, NEW YORK, N Y

From the Neurological Institute and the Neurological Department of the Vanderbilt Clinic New York City

THE use of quinine hydrochloride therapy in multiple sclerosis has given sufficient promise of benefit to warrant its being reported The theory upon which the treatment rests, as well as a tabulation of results obtained thus far, is described elsewhere (1,2) This communication will be concerned with the technique of administration of quinine, a procedure in which there are certain complexities, and which requires considerable care and constant supervision

At the outset, in the treatment of a patient with multiple sclerosis, one is likely to be pessimistically biased It is necessary for the physician to subordinate such prejudices as rigidly as he would a leaning toward undue optimism Quinine therapy in this disease is not only lengthy, but is beset by ups and downs which would, ordinarily, be too apt to cause a too early discontinuance of the therapy Quinine itself produces mild symptoms of toxaemia, which can in their turn, bring about accentuation of the signs of the multiple sclerosis,—a situation which requires recognition The disease, even aside from its tendency toward spontaneous remission, runs a course in which there are also daily fluctuations in the severity of the symptoms

The hydrochloride was chosen as the quinine salt to be used because it is the most soluble of the available preparations The initial dosage is five grains, three times a day This dosage, however, requires frequent alteration and the circumstances determining the changes demand continuous vigilance It has been found necessary that patients arrange to be seen at a minimum of once weekly, at least during the first two months of treatment All of the patients in the series have been able to manage to be seen thus frequently, even though the trip has sometimes been a troublesome one A few have found it simpler to be hospitalized for the initial period The therapist should also be available by telephone so that changing indications between visits can be promptly attended to

In assessing the merits of quinine treatment it has, of course, been necessary to try to distinguish between spontaneous remissions and therapeutic results The details concerning this distinction are given in the communication already referred to (2) The best criterion available has been the fact that most of the improvements under quinine treatment have occurred at a definite interval after the regimen was started,—namely, three to five weeks As would be anticipated, the improvements have been related to particular symptoms rather than to the patient as a whole Naturally, improvement is most apt to occur in the youngest of the symptoms of any particular patient, and there are a number of instances in the series in which the younger symptoms have disappeared, while the older ones have remained uninfluenced The best prognosis has been of symptoms about eighteen months old, or less However, many of those which are older have also responded,—usually after a treatment interval of several months Hence it will be seen that the patient must, in this instance, be looked upon rather as a group of symptoms than as a whole,—a necessary violation of the modern and generally satisfactory viewpoint For this reason, it has been found useful to take histories in a strictly chronological manner The following blank has been utilized, and from it, prognostic determinations can sometimes be made with fair accuracy

HISTORY BLANK

SYMPTOM	Date of Onset	Date of Remission	CHARACTER OF SYMPTOM	Previous Treatment	Date and Effect of Treatment
1st symptom					
2nd symptom					
3rd symptom					

Technique of Treatment

The initial dosage, as already stated, is fifteen grains of quinine hydrochloride daily,

* Read at a meeting of the Neurological Section of the Medical Society of the State of New York June 3, 1930

by mouth, in three capsules of five grains each. The majority of the patients will tolerate this dose, but in some, the amount must be greatly reduced. One must watch for symptoms of cinchonism; the chief ones are ringing in the ears, a feeling of fullness in the ears or head, mild neausea, headache; it is unusual to find all four symptoms in the same patient. The onset of even the mildest cinchonic symptom is the signal for temporary termination of quinine administration. The drug should be omitted for three to four days, after which it should be reinstated, usually in the same dose; it will frequently be found that an increased tolerance has been developed by the patient. If this has failed to occur, a smaller dose must be used. The following are the dosages which have been found most useful; the method of trial and error is the only one by which the correct amount can be properly estimated: five grains twice a day, five grains once a day, fifteen and ten grains on alternate days, fifteen and five grains on alternate days, ten and five grains on alternate days, two grains three times or twice or even once a day, five and two grains on alternate days. Occasionally it has been useful to give fifteen grains one day, ten the next, five the next, and no quinine the next; on the following day the cycle has started again with fifteen grains.

Since cinchonism will invariably accentuate the symptoms and completely block progress toward improvement, it is of first importance to detect it and to grade the dose according to the tolerance of the particular patient. In a series of more than twenty five patients, no two have had the same regimen, and no one has been maintained on an unchanged regimen for more than a few weeks.

Occasionally it is wise to interrupt the medication for three or four days without awaiting cinchonism, merely on the principle of giving the patient a rest from therapy. After patients have been on quinine for some five months or more, it is also wise to cut the dose down to the smallest amount compatible with maintenance of improvement. Too long an omission and too small a dose are both harmful, however, since patients sometimes slip back under such circumstances. No definite minimal dose can be described; it must be determined separately for each patient.

An occasional individual will be found who can tolerate larger doses than fifteen grains a day. In such instance, in the early weeks of treatment, twenty or twenty five grains a day may be given over short periods. On the other hand, situations are met with in which either there are profound emotional disturbances due to the disease itself, or there is an accompanying psychoneurosis. In either case the embarkation upon a new form of treatment may be marked by so severe an emotional reaction that the use of the therapy itself is threatened. In the two such instances thus far encountered, hospitalization for a week has been effectual in settling the patient sufficiently to permit of the institution of a regimen.

Rarely, patients will grow worse during the first one or two weeks of treatment, without cinchonism. In these cases, omitting the quinine for a week, with reinstatement of it at fifteen grains a day has caused the curve to change its direction and improvement has commenced. There are four factors which have accounted for regression during treatment: extraneous infections, such as boils, colds and grippe, the premenstrual or menstrual epochs, physical traumata and severe constipation. In the eighteen months of experience which we have had with quinine, one of these conditions or cinchonism has always been found to exist, with the exception of three symptoms in three very old patients; in these instances regression occurred for unknown reasons. With these three exceptions, there have been none but transitory regressions, correctly accounted for, and easily controlled. On the other hand, not all of the patients have improved.

Satisfactory improvement has been seen in symptoms as old as five years, but no symptom older than that has undergone any change. It is, of course, unfortunate that the symptoms with the best prognoses may not be the ones in whose cure the patient is most interested.

It is important to be certain that the patient is actually receiving the proper preparation. In the present series, all the quinine prescriptions have been filled at the same pharmacy, and it has been possible to have such assurance.

There is no evident indication for the intravenous use of quinine. The oral method gives the slow, fairly continuous absorption of the material which is probably preferable to a rapid instillation with evanescent effects.

There is no theoretical reason for considering that the treatment should be anything but continuous and permanent. Nothing has been learned, thus far, which permits of stopping quinine permanently and the present indication is that the patients will have to continue taking it indefinitely.

SOME CONSIDERATIONS OF THE ETIOLOGY AND TREATMENT OF OBESITY

By C. W. NISSLER, M.D., EN SHUI TAI, M.D., AND BURGESS GORDON, M.D.,
PHILADELPHIA, PA.

From the Medical Service of Dr. Thomas McCrae and the Department for Diseases of the Chest, Jefferson Hospital.
A part of the expense for this investigation was defrayed by a grant from the Lessing J. Rosenwald Fund.
Read before a meeting of the Section of Medicine, College of Physicians, Philadelphia, Pa., Feb. 23, 1931.

THE consideration of obesity would be simplified if all cases could be explained on the basis of disturbance of the endocrine glands or excessive feeding and restricted exercise. The objection to such generalization is obvious. The failures in treatment indicate that management is difficult or that some mechanism must be explained before the problem is understood satisfactorily. This is emphasized in patients with so-called endogenous obesity, who fail to lose weight following the administration of glandular extracts and others with so-called exogenous obesity, who do not respond to reduced caloric intake and increased exercise.

In reviewing previous studies on overnutrition the most frequently discussed mechanisms are basal metabolism, water balance, respiratory quotient and the influence of heredity. There is almost general agreement that obese subjects require less food for maintenance of excessive fat than individuals of normal weight and there is a tendency to convert readily into fat the overabundant supply of food. According to McLester[1] the metabolic rate in adults, except in such conditions as myxedema and so-called adiposo-genital dystrophy, is essentially normal. In agreement with this are the findings of Topper and Mulier,[2] who note that the basal metabolism of overweight but otherwise average children is usually normal, with a tendency, in fact, toward a high normal level. It appears in the reports of other workers that a characteristic disturbance of metabolism may be disregarded in over-nutrition. This is especially significant in children because growth and increased activity of the sexual glands occur during the prepubertal period and yet so far as determined there is no typical variation in the metabolic rate. If important disturbances occur, it would be extremely hazardous to differentiate between variations in simple obesity and those resulting from involvement of the endocrine glands. In studies of the respiratory quotient Strause and his co-workers[3] found that the obese patient does not receive from his food the same specific dynamic action which the normal individual experiences. Additional evidence suggesting a departure from normal in the manner in which nutritive materials are metabolized is reported by Krantz and Means.[4] This refers especially to the stimulating effects of epinephrine on the metabolism of obesity. They state: "The respiratory quotient rises definitely less in obese patients than in normal subjects. This difference suggests that the obese oxidize a relatively greater amount of fat after epinephrine injection than do normal individuals." At present it is perhaps a matter of conjecture whether or not the respiratory quotient in the obese child is the same as the adult and if there is a difference the question of time and manner of onset is raised. DuBois[5] remarks pertinently that the explanation of the phenomenon of maintenance of normal weight under marked variation in bodily activity and food consumption would be an important step in solving the problem of obesity.

However the condition may be regarded physiologically the fact remains that overweight is potentially a serious disorder. It may be a forerunner of diabetes, a contributing factor in gall bladder disease, disturbances of the circulation, nervous manifestations and infections. And even more serious perhaps are the catastrophes that follow haphazard methods, fads and fancies in reducing the body weight. It seems that the unsettled knowledge of obesity justifies speculation.

In a report from the Chest Department of the Jefferson Hospital in 1928 it was suggested that a disturbance in sugar metabolism was possible factor in obesity.[6] An hypothesis was constructed from data obtained in comparing symptoms experienced by long distance runners[7,8] with those of obese individuals on restricted carbohydrate intake.[6] In certain individuals there were hypoglycemic-like manifestations accompianed by moderate reduction in the level of blood sugar. The response to small doses of readily available carbohydrate (increased strength and decreased hunger) was definite in several instances. The return of the blood sugar to normal occurred, but, in degree of responsiveness, was less striking than the cessation of hypoglycemic-like symptoms. The following questions were raised. Do certain obese individuals experience transient hyperinsulinism induced, as Harris[9] suggests, by habitual and excessive carbohydrate feeding? Is the tendency to restrict exercise a natural effort of the patient to prevent the occurrence of hypoglycemic-like manifestations? Is a vicious circle created in which overindulgence in carbohydrate and excessive insulin production are closely related? The latter because of excessive carbohydrate, the former induced by

excessive insulin? Or stated in another way: In the beginning the potential obese patient eats excessively because of pleasure and example. This is followed by an acceleration in the production of insulin which further influences the patient to increase the intake of carbohydrate. The result is a step-up in the output of insulin. The more insulin, the more starch; the more starch, the more insulin. Less work is attempted because exercise induces hypoglycemic-like phenomena. The ultimate effect is lassitude and the accumulation of unused fuel in the form of fat. If this is true a decrease in function of various glands, if such occurs, may be the result rather than the cause of obesity.

There are certain features in the hypothesis that may be considered without undue speculation. Of special interest is the effective use of repeated doses of insulin in malnutrition, as reported by Apple, Farr and Marshall[10] which suggests that gain in weight may be influenced artificially (hyperinsulinism) in a manner not unlike that considered in the present hypothesis. The question of heredity may also throw light on the problem. In a study of the immediate ancestry of over 500 obese women it was found that heredity was considerably less important than example and custom in eating. As to the history of exercise a sharp decline in the amount of work was noted with the corresponding trend in accumulation of body fat. Hunger and weakness during exertion were frequent, especially when starch had been used to excess for a number of years. The tabulation of food intake showed a high consumption of starch derived largely from cereals; the use of fat and protein was usually within normal limits. The charts indicated a wide variation in the daily intake. This was due, in part, to the individual's desire to reduce; it being his impression that this could be accomplished if only one meal was taken daily. These data indicate that very few patients continued on rigorous diets for any considerable period of time. Furthermore, the average daily caloric intake for one-two weeks was usually high, whereas on a single day it was frequently less than 500 calories. The figures on the sugar content of the blood showed that about 55 per cent were within normal limits; 15 per cent varied between 65-88 mg. per 100 cc. of blood and the remaining number were above 120 mg. The highest levels (175-285 mg.) occurred in patients with the longest history of excessive carbohydrate feeding. As for example, a patient 20 years of age, weighing 124.6 kg. showed a blood sugar of 254 mg., and her sister, 9 years of age, weighing 72.4 kg. had a content of 106 mg. In another family the mother, age 38, weighing 109 kg., the blood sugar was 285 mg. and in her daughter, 12 years of age, weighing 92 kg., the level was 112. In general, the normal or subnormal blood sugar levels were more common in individuals with recent histories of overindulgences. The lowest figures were noted most frequently in obesity of 2-3 years duration and in these hypoglycemic-like manifestations were most striking. On exercise there were several instances of transient reduction in the sugar level of from 5 to 20 mg.[11] However, such variations were not regarded as always indicative of the actual need for readily available carbohydrate since there were numerous patients (some with marked hyperglycemia) who suffered hypoglycemic manifestations and were relieved by dextrose. An explanation for this may be suggested in the report of Foshay,[12] who states that the blood sugar level may not correspond to the content of sugar in the tissues.

In further consideration of the hypothesis it may be suggested the effects of the so-called dextrose-moderately-low starch regimen,[6] the primary purpose of which is to reverse the vicious cycle as described. The regimen is as follows: The coperation of the patient is obtained through his own tabulations of symptoms and the daily intake of food at meal time and between meals. He is advised not to change his usual diet or habits in any way. When sufficient records have been obtained for a critical study of symptoms and dietary habits the customary intake of carbohydrate is reduced two-thirds. No change is made in the number of meals or in the previous consumption of fat, protein or water. So far as possible the total intake for lunch and dinner is equally divided. In order to relieve hunger and weakness and to provide sufficient calories between 20 and 40 gm. (82-164 calories) of dextrose* (Corn Products Refining Co.) are administered daily in divided doses (2-4 gms. every half hour from 9:30-11; 2:30-5; 8-9) between meals. It is assumed that this plan of administration of carbohydrate provides readily available energy so that the reduction in the amount of starch at meal time may be accomplished without disturbance. The patient is advised to walk regularly from one-half to one mile daily.

A satisfactory reduction in weight has been accomplished in over 65 per cent of women, the average loss being 1.5 kg. weekly. The failures have occurred usually in the uncooperative patients and those with considerable muscular development of the arms, legs and

* The lozenges are manufactured by Smith, Kline and French Laboratories, Inc., 105 N. 5th Street, Phila., Pa. The lozenges weigh 2 gm. each and are flavored with peppermint, lime, wintergreen and lemon.

buttocks So far as determined there have been no untoward effects other than a few instances of wrinkles in the older women, transient headaches at the beginning of the diet, constipation and a sensation of fullness in the stomach if the dosage of dextrose was excessive The majority have been free from mental depression and craving for carbohydrate A fairly constant reduction in high blood sugars (30 60 mg) was not uncommon following a loss in body weight In reviewing the events of patients treated over two years ago, it is perhaps interesting to note thirty-four instances of loss of 15-30 kg with relief from symptoms and no considerable gain in weight In these the fluctuations in blood sugar are essentially within normal limits

Obviously the hypothesis suggesting a disturbance in the sugar regulating mechanism in obesity is largely speculative Fallacies arising from errors in tabulation of food, conditions that may have influenced the blood sugar levels and possible effects of dextrose on diuresis and specific dynamic action, cannot be disregarded It would appear, however, especially in considering the results in treatment, that merely a redistribution of the total intake of carbohydrate favors a reduction in weight and relieves the abnormal desire for food This may suggest that calories as derived from starch are more responsible for the accumulation of weight than the excessive intake of fat, protein or water, that the occurrence of symptoms may actually be increasingly aggravated by overindulgence It would appear that a dietetic plan which provides readily available energy, as required for work is more helpful in treatment than rigid restriction of food and the use of glandular extracts

CONCLUSIONS

1 It appears that obesity is due primarily to decreased physical effort and the prolonged excessive intake of starch A disturbance in the sugar regulating mechanism due essentially to over-stimulation and "intoxication" is suggested as a contributing factor

2 It is suggested that disturbances of the endocrine glands are the results rather than the primary cause of overnutrition

3 A regimen consisting of a reduction in the usual intake of carbohydrate at meal time and the administration of dextrose in divided doses between meals apparently favors the loss of weight and the cessation of abnormal desire for food

VIOSTEROL IN THE TREATMENT OF PSORIASIS

By SAMUEL MONASH, M D , NEW YORK, N Y

From the Department of Dermatology College of Physicians and Surgeons, School of Medicine of Columbia University, New York and the New York Skin and Cancer Hospital

It is a well known fact that psoriasis is not nearly so commonly met with in the tropics as it is in the temperate zone Whether this is due to the greater heat prevailing longer exposure to the sun, greater skin pigmentation or differences in diet are matters for experimentation and speculation The frequent beneficial results of sunlight and of ultraviolet radiation suggested the possibility of the disease being due to a deficiency in Vitamine D

In order to determine whether this were true, a number of psoriatics were treated with irradiated ergosterol or viosterol, the dosage given being 15 to 20 drops daily The patients were given either no local treatment or only boric acid ointment In four of the cases, while the patients were actively taking the viosterol, one for a period of two weeks one for six weeks and two for two months, new lesions appeared Since the dosage was a moderately large one, the outcrop

ping of new lesions tends to show that psoriasis is not due wholly to a deficiency of Vitamine D. Details of the cases follow:

Case No. 1: Mrs. A. G., age 44, guttate type, present on and off for the past eight years.

Date	Remarks	Dosage	Other Treatment
Sept. 20, '29		15 drops	None
Oct. 4	No change	20 "	"
Oct. 16	No change	20 "	"
Oct. 30	Lesions lighter	20 "	"
Nov. 20	Most lesions are improved, but few new guttate lesions have appeared on left leg in past week.		

Case No. 2: Mrs. I. W. G., age 39, generalized pea to quarter sized lesions, present on and off for the past nine years; disappears in summer on exposure to the sunlight, reappears in the winter.

Date	Remarks	Dosage	Other Treatment
Sept. 27, '29		20 drops	None
Oct. 23	Much improved..	20 "	"
Nov. 13	New guttate lesions have appeared on legs and forearms...	20 "	"
Dec. 11	No new lesions since last visit. Old lesions on arms have disappeared	20 "	Ung. Ac. Boric.
Feb. 24, '30	Lesions practically all gone. No recurrence until Sept. 25, seven months later, when she was given generalized alpine light therapy with marked improvement.		

Case No. 3: Mr. I. S., age 26; gyrate lesions over elbows, knees and back, present for the past three years.

Date	Remarks	Dosage	Other Treatment
Sept. 22, '30		15 drops	None
Oct. 22	Slightly improved....	20 "	"
Nov. 26	New lesions have appeared in the past two weeks.		

Case No. 4: Mrs. M. R., age 48; half-dollar circular plaques over knees and elbows for the past year; at present, in addition, acute generalized exacerbation.

Date	Remarks	Dosage	Other Treatment
Nov. 15, '29		15 drops	None
Dec. 2	Few new lesions on legs	20 "	Ung. Ac. Boric.
Dec. 23	No new lesions since last visit. Not much change in lesions	20 "	" " "
Jan. 6, '30	Slight improvement.		

The above case histories show distinctly that psoriatic lesions can appear in patients to whom has been supplied a considerable quantity of Vitamine D in the form of Viosterol. While following the patients, however, I was impressed by the fact that in general they showed some improvement under the treatment. This was especially true in Case No. 2 and still more so in the following cases:

Case No. 5: Mrs. E. G. M., age 31; generalized guttate lesions, present for the past 16 years.

Date	Remarks	Dosage	Other Treatment
Sept. 25, '29		20 drops	None
Oct. 2	No change	15 "	"
Nov. 13	Lesions involuting	15 "	Ung. Boric. Ac.
Dec. 11	Still improving... Lesions almost all gone.	20 "	" " "

Case No. 6: Miss E. F., age 9; guttate patches over elbows and knees for past four years; usually improved in the summer and under ultraviolet therapy.

Date	Remarks	Dosage	Other Treatment
Oct. 21, '29		15 drops	None
Nov. 13	Slight improvement	15 "	"
Dec. 2	Much improved. A few lesions have disappeared	15 "	Ung. Boric. Ac.
Jan. 21, '30	All lesions gone.		

Case No. 7: Miss L. L., age 19; generalized guttate lesions of one year's duration.

Date	Remarks	Dosage	Other Treatment
Oct. 2, '29		15 drops	None
Nov. 13	Much improved, all lesions involuting.		

During the past year I have been combining the use of viosterol with the usual anti-psoriatic ointments and have been much pleased with the results. The lesions present seemed to involute at a faster rate than under ointment therapy alone. As an adjuvant in the treatment of this stubborn and widespread disease, especially in those cases which are benefited by sunlight or ultraviolet light, the use of viosterol can be recommended. No untoward results were noted from its use in the dosage given over a period of months; however, it would be wise to give the drug for two months and then interrupt the treatment for a month before giving it again to prevent any possible symptoms of overdosage in sensitive patients.

THE VALUE OF THE ASCHEIM-ZONDEK TEST TO THE GENERAL PRACTITIONER*

By WILLIAM FILLER, M D, NEW YORK, N. Y.
From the Department of Gynecology, Bellevue Hospital, New York

OF the innumerable tests that have been brought forth for the diagnosis of pregnancy, the Ascheim-Zondek test is, by far, the most accurate and valuable in its application. My purpose in this paper is not, however, to present a series of cases to confirm the accuracy of the test. Its almost 99 per cent accuracy has been confirmed the world over. Nor do I intend here to dwell at length in the field of theoretical speculation, except as it directly concerns the practical application of the test by the general practitioner. My principal aim will be to present the Ascheim-Zondek test as a valuable adjunct to the diagnostic armamentarium of the general practitioner.

Forty cases in which the diagnosis of pregnancy was the point in question serve as the basis of this paper. With the exception of a few cases which were drawn from the Gynecological Division of Bellevue Hospital because of their rarity and intrinsic interest, these cases come from the offices of my colleagues. On the urine of each of these forty cases, I personally conducted an Ascheim-Zondek test, using the unmodified technique originally suggested by Ascheim and Zondek.

According to this technique, a voided morning specimen of urine, before any intake of food or fluid, is obtained from the patient. It should be collected in a clean bottle. Sterile specimens are not necessary. It is essential to impress upon the patient that she is to take no drugs for 24 hours previous to the collection of her urine, as the mice used in the test are very susceptible to drugs especially alkaloids. Five infantile female mice are used for each test. The mice should be approximately 3 weeks old and weigh about 6 grams. The mice receive six injections subcutaneously, laterally in the back, three on the first day—and three on the second, allowing a lapse of at least three hours between injections. With each injection, 2 cc of the urine is administered to mouse number 1; 25 cc to mouse number 2, 3 cc to mouse number 3 and mouse number 4, and 4 cc to number 5. One hundred hours after the first injection, the mice are killed with the illuminating gas and laparotomized. (Extensive experiments on mice which have been done by Ehrhardt to determine whether the test could be completed in a shorter time have thus far proved unsuccessful.) Friedman and Schneider have obtained results in 24 to 48 hours by the intravenous injection of urine into female rabbits.

The ovaries of untreated infantile mice are pale grayish pink in color and about the size of a pinhead. If the laparotomy discloses that all the ovaries have this appearance, the test is negative for pregnancy, regardless of the condition of the uterus. A positive result is recognized by the enlargement of the ovary to two or three times its normal diameter, and by its distinctly red or reddish pink color. This is accompanied by three definite reactions. Anterior pituitary reaction 1—Normal ripening follicles (ovulation reaction), anterior pituitary reaction 2—The ovaries grossly show the presence of fine purplish dots which correspond to hemorrhages into normal and abnormal follicles, and are apparently due to the intense congestion set up by the hormone (hemorrhagic cyst reaction), anterior pituitary reaction 3—The ovaries present a process of luteinization of the cells of follicles and the formation of abnormal structures resembling corpora lutea in which ovulation has not occurred and the ovum remains imprisoned. This may appear macroscopically as subiliary yellowish protrusions on the surface of the ovary (luteinization reaction).

Zondek has shown that the appearance of anterior pituitary reaction 1 alone is not characteristic solely of pregnancy. Consequently anterior pituitary reaction 1, unaccompanied by anterior pituitary reaction 2 and anterior pituitary reaction 3, is to be regarded as negative for pregnancy. The appearance of anterior pituitary reaction 2 and 3, even though they be present in only one ovary of the five mice used, is taken as positive evidence of the existence of pregnancy.

For the sake of clarity, I have divided the forty cases used in this series into five groups. The first and largest of these falls under the general heading of Early Suspected Pregnancy. The typical case in this class complained of delayed menstruation. In some cases, this was associated with other presumptive signs and symptoms of pregnancy. However, in the majority of cases, delayed menstruation was the only reason to suspect pregnancy. In the entire group, there were 20 cases, of which I found 10 negative and 10 positive results. The results in all twenty cases were later checked with the individual physician and proved, with the passing of time, to be prophetic. In some of the non-pregnant cases, I feel quite confident, after communication with their physicians, that by reporting these women negative for pregnancy so early I saved them, notwithstanding their physicians' admonitions against such practice, from the hands of unscrupulous abortionists and midwives.

Two cases in this group deserve special mention. *Case Number* 1—H M—age 42—married 3 years—gravida 0. Menstruation established at

* Read before the Bellevue Medical Society, February 2, 1931.

14; always regular. Last regular period in July, 1929. Missed August and September periods. Fearing pregnancy so late in life, she landed in the hands of an abortionist who graciously performed a dilatation and curettage. Following this, periods were irregular, occurring at 6 to 7 week intervals, until May. Missed May, June and July. This time she decided to consult a neighborhood physician before having another dilatation and curettage. She was tremendously obese, and, upon examination, the size of her uterus could not be determined with any accuracy. Morning nausea was present. The physician prevailed upon her to have an Ascheim-Zondek test done, which proved to be negative. It is now 10 months since she has menstruated and she still shows no signs of pregnancy. The value of the Ascheim-Zondek test in this is self-evident.

Occasionally, the urine of women in the menopausal period will produce an anterior pituitary reaction 1, so that if this reaction appears and the clinical history of the patient justifies it, the test should be repeated and the appearance again of only anterior pituitary reaction 1, should be taken as conclusive evidence of the absence of pregnancy.

Case Number 2—A.M.—age 29—last regular period August 24. Date of conception known to be September 1. Urine was obtained on September 24, one day after her period had failed to appear. The test proved to be positive after what was definitely known to be only a 23 days' gestation. This was the earliest positive test we got in our series, and, as far as we know, is the earliest Ascheim that has been reported in literature.

The reliability of the test is undoubted in a pregnancy that has existed more than four weeks. We have had a case in this series that was negative when the patient had missed her period one week, but because the patient was suspicious clinically of pregnancy, the test was repeated later. This time, it was found to be positive. Thus, the occasional appearance of a negative result in a case of very early pregnancy may easily be checked up by repetition of the test, because even in early pregnancies, before any positive signs have appeared, a persistent negative never occurs.

In the second group, I have included those cases in which the chief complaint has been Anomalous Bleeding, associated with other symptoms or definitely palpable adnexal pathology. There were 6 cases in this group. In 5 of the cases, a provisional diagnosis of ectopic pregnancy had been made, only 2 of which later proved to be ectopics. One of these cases gave us a positive Ascheim-Zondek. The other, an old ruptured ectopic, ruptured at least three weeks, gave us a negative result. Ascheim and others have demonstrated that the test will be positive as long as there is living placental tissue in biologic contact with the maternal blood. The test, therefore, has its greatest field of value in unruptured ectopic pregnancy, as it will give a positive reaction only when the embryo is alive or not longer than 8 to 10 days after its death. We might state here that the appearance of a positive Ascheim-Zondek during pregnancy is no indication as to the viability of the fetus. However, Stal has shown that in pathological pregnancy, the appearance of a negative Ascheim-Zondek is definite indication that the embryo is dead.

Because of their interest, I have chosen three case histories from this second group. *Case Number* 1—L.S.—age 19—single. Last regular period August 3. On August 10, had intercourse. On August 15, began to suffer from frequency of urination, burning, leucorrhea, and pain in both lower quadrants. Was examined August 17, and found to have acute urethritis, endocervicitis, bilateral salpingitis, and retroverted uterus. Smears taken from her urethra and cervix showed gram-negative intra-cellular diplococci. On September 1, bled scantily for one day, although she had always bled four days, with a moderate flow. On October 8, she complained that she still had not had her period, it being about nine days overdue. She also gave a history of morning nausea. On examination, the uterus was retroverted, slightly boggy and enlarged and adherent to palpably enlarged adnexal masses. She had colostrum in her breasts. An Ascheim-Zondek test was done and found to be negative. On October 15, she began to menstruate. My assumption in this case was that her anomalous menstruation and the colostrum in her breasts were due to the inflammatory condition in her ovaries and not to any abortive pregnancy.

Case Number 2—H.M.—age 22, married. Had a regular period June 28. Missed July and August periods. On September 1, complained of slight pains in the right lower quadrant and spotting. On examination, cervix was eroded, uterus was normal in position and size, and there was a tender adnexal mass on the right side. Provisional diagnosis of ectopic pregnancy was made. Patient objected to immediate operation because of the apparent insignificance of her symptoms. An Ascheim-Zondek test done was positive. An operation was then insisted upon and disclosed a right-sided, unruptured ectopic.

Case Number 3—L.P.—age 30—married. On December 2, patient was injured slightly in an automobile accident. However, she began to complain, soon after, of severe pain in the left lower quadrant. On examination, showed a left-sided mass. Menstrual history normal. Ascheim was negative. Patient operated upon, however, with provisional diagnosis of ectopic pregnancy, before the report of the Ascheim test was ready. The operation revealed a left-sided, chronically swollen and inflamed tube and ovary.

We come now to the third group in our series. In this group, I have placed those cases in which the chief complaint or finding on examination was an Enlarged Uterus. The differential in these cases has been between fibroid and pregnancy. There were 11 cases in this class, and all of them were gratifying in their accurate differential between fibroid and pregnancy.

I have selected 3 cases from this group as illustrative. *Case Number* 1—R.O.—age 44—gravida 11, para 8—had not been pregnant for nine years. Last regular period February, 1930. Bled scantily in March and April at her expected time. No presumptive symptoms. Insisted that she was not pregnant. On examination, uterus was the size of a three months' gestation. Ascheim-Zondek test done and found to be positive. Patient delivered of a normal baby in December.

Case Number 2—Q.O.—age 38—married 9 years—never pregnant. Last regular period May 8, 1930. Was scant; duration 4 days. Had been having hot flushes for last month. No presumptive signs or symptoms of pregnancy. On examination, uterus was enlarged to about 20 weeks' gestation. Ascheim-Zondek test done and proved to be negative. Had no bleeding in June or July. Patient operated upon with diagnosis of fibroid. Post-operatively, the diagnosis was confirmed.

Case Number 3—R.L.—age 39—married 15 years—gravida 3, para 3. Last pregnancy 7 years previous. Had been having regular menstrual periods. No history of amenorrhea. On examination, uterus was enlarged to about 10 weeks' gestation. Diagnosis of fibroid was made. Patient was operated upon. When the abdomen was opened, the uterus was found to be uniformly enlarged and soft and gave all indications of being an intrauterine gestation. The abdomen was closed without further manipulation. An Ascheim-Zondek test was requested, post-operatively. The test proved to be negative. Patient began to menstruate the sixth day post-operatively, the day of her expected regular period. We feel that the patient had a soft sub-mucous fibroid which is often difficult to differentiate from pregnancy, even when the abdomen has been opened. Together with this case, there was another one with an almost identical history. An Ascheim was done pre-operatively and found to be negative. Upon operation, the uterus was discovered to be quite soft and enlarged to the size of a three months' gestation. When opened, it revealed a soft intra-mural endometrioma filled with thick chocolate-colored fluid. We feel that the value of the Ascheim-Zondek test as revealed by these two cases can not be over-emphasized.

In considering the differential diagnosis between fibroid and pregnancy, we do not intend to minimize the judicious use of the *x*-ray in the diagnosis of pregnancy. Matthews has shown that an 85 per cent accuracy was obtained with the *x*-ray in cases of pregnancy between 16 and 18 weeks' gestation, and 100 per cent after 18 weeks' gestation. However, the superiority of the Ascheim-Zondek test is striking. First, it has an accuracy of 98.6 per cent after 4 weeks' gestation; second, it is done with no inconvenience to the patient; third, although the *x*-ray is safe so far as its effects upon the fetus are concerned, when given in the proper doses and by competent hands, the factor of safety plays no part whatsoever in the performance of the Ascheim-Zondek test.

In our fourth group, the Ascheim-Zondek test plays even a greater role, not only because of its diagnostic, but also because of its prognostic value. In this group, we have placed cases of Hydatidiform Mole and Chorioepithelioma. We have only 2 cases in this group, both of these hydatidiform moles obtained from the Gynecological Division at Bellevue Hospital.

Case Number 1—A.V.—age 21—gravida 1, para 0. Chief complaints, vaginal bleeding and abdominal pain after a period of two months' amenorrhea. On examination, there were grape-like masses protruding from the vagina. Pathological examination showed hydatid degeneration. Patient was curetted. Ascheim-Zondek test was done one day following the curettage. Test was positive. Two weeks later, another Ascheim-Zondek was done after complete subsidence of symptoms. This time the test was negative. Patient was discharged, cured.

Case Number 2—A.K.—age 44—gravida 10, para 8. Chief complaint, vaginal bleeding. Last regular period, June 10. Skipped July. Bled August 7 and 8. Week later, bled again for two or three days. At this time, a hard mass the size and appearance of a fist, presented itself at the vulva. Pathological examination revealed a hydatidiform mole. On September 23, patient was curetted; bleeding stopped after one week when she was discharged from the hospital. On October 22, while at home, patient began to bleed again and complain of marked weakness. Passed large clots on October 30. Readmitted to hospital. On examination, fundus was slightly enlarged. No adnexal pathology. Ascheim done and found to be negative. *X*-ray therapy given. A second Ascheim, performed after *x*-ray therapy, was also negative. Because of the continuation of bleeding, radium was inserted into the vagina. When radium was inserted, no curettage of the uterus was attempted, because of its extreme softness. Consequently, no curettings were obtained for examination. On what little examination was done at this time, there was no irregularity in the contour of the uterine cavity. Another Ascheim was done after radium and found to be negative. Repeated [illegible] Vaginal bleeding ceased [illegible] o improve and she was fi[illegible]ough the possibility of chorioepithelioma was considered, its

presence was eliminated by the persistence of the negative Ascheims. The service rendered by the Ascheim-Zondek test was immeasurable in that it enabled us to discharge the patient with the reasonable assurance that she was cured. Ascheims will be continued on this patient for over a considerable period to check up on any possible further developments.

A review of the literature on the subject repeatedly demonstrates the infinite value of the Ascheim-Zondek test in the diagnosis and prognosis of hydatid mole and chorioepithelioma. Rossler, Schultze-Rhonhof, Mack, Catherwood, Ehrhardt, Ascheim, Zondek, and Steckel have contributed valuable data in this connection. Rossler reports a case of a woman who had had a hysterectomy performed for chorioepithelioma. One and a half years later she gave evidence of metastatic involvement. An Ascheim-Zondek test done at this time was strongly positive. Patient died and autopsy revealed generalized chorioepitheliomatous metastasis. Mack and Catherwood report a case of chorioepithelioma with a positive Ascheim-Zondek after a complete hysterectomy had been done and the patient was free of symptoms. Two months later, metastasis appeared on the anterior vaginal wall. The patient was treated with radium and the Ascheim-Zondek test became negative. Later, the Ascheim-Zondek test was again positive. They lost sight of the patient—but their assumption, which we feel to be correct, was that the patient was not cured. Ehrhardt reports a case of a woman of 30 with a history of having expelled a hydatidiform mole two years previous to the onset of her present illness. She now had symptoms of a brain tumor. Gynecological examination revealed either a pregnancy or a chorioepithelioma. An Ascheim-Zondek test was strongly positive even in diluted urines showing high hormonal content. This seemed to favor the presence of a chorioepithliomatous pregnancy. Trepanation was done and the patient died. Autopsy showed chorioepithelioma and generalized metastasis.

An Ascheim-Zondek test is positive in cases of hydatidiform mole and chorioepithelioma in dilutions of the urine as high as 1 to 10. Occasionally, one may obtain a positive reaction in a hydatidiform mole even after expulsion of the mole, sometimes as long as two months after the expulsion, without evidence of chorioepitheliomatous changes. Ascheims should be done as a matter of post-operative routine on all cases of hydatidiform mole and chorioepithelioma every two weeks until the test appears negative.

In our fifth group, if group it can be called, we have only one case. This case we have isolated into a group because of its potential significance

Case History—L.M.—age 40 — married 17 years—gravida 0. Irregular menstrual periods since onset at 13. Last regular period August 26. Skipped period due September 23. On October 2, in order to determine whether or not she was pregnant, an Ascheim was done which proved to be positive. Began to bleed on October 10, the character, amount, and duration similar to a normal menstrual period. Because, in our series, we had never obtained a positive Ascheim in any case other than pregnancy or hydatid mole, we felt that this patient had a very early abortion. Unfortunately, we were unable to obtain a urine following her menstrual period.

From a personal communication with Dr. Ralph Kurzrok of Sloane Hospital, we learned that he too had obtained several such cases in which positive Ascheims had occurred in cases of prolonged sterility where the patient had gone over her period anywhere from a few days to a few weeks, but had later menstruated as usual. In these cases, Ascheims repeated after menstruation were found to be negative. All these cases had no apparent cause for their sterility. We feel, therefore, that there must be a type of sterility in which impregnation of the ovum by the spermatozoa does occur, but, through some defect, implantation into the uterine wall either does not take place or is of brief duration and an early unsuspected abortion follows.

With this point in view, it is advisable to study those cases of sterility of unknown etiology and the application of the Ascheim-Zondek test here may open the way to a still undiscovered field.

In conclusion—

1. Our series of cases has confirmed the accuracy of the Ascheim-Zondek test as obtained by previous investigators. Our accuracy was 95 per cent.
2. We have demonstrated the use of the Ascheim-Zondek test as a diagnostic aid to the physician,
   a. in making a positive diagnosis of pregnancy earlier than through any other means.
   b. in differentiating menopause from pregnancy.
   c. in differentiating ectopic pregnancy from adnexal disease.
   d. in differentiating fibroid of the uterus from pregnancy.
   e. in the diagnosis and prognosis of hydatid mole and chorioepithelioma.
   f. in the possible discovery of a cause of hitherto unexplainable sterility.

I wish to express my thanks to Dr. Frederick C. Holden for his constructive criticism and his kind cooperation in furnishing material for this article.

I also wish to thank Mr. Joseph M. Chernaik for the use of his laboratory and his able assistance in conducting these tests.

ELECTRODESICCATION OF TONSILS HARBORING MONILIA KRUSEI (CASTELLANI) AND NONVIRULENT DIPHTHERIA BACILLI

By EDGAR R MAILLARD, M D, NEW YORK, N Y

From the Division of Laboratories and Research New York State Department of Health Branch Laboratory New York N Y

* Presented at the meeting of the New York State Association of Public Health Laboratories Albany, November 7, 1930

A HIGH SCHOOL girl, sixteen years of age, in the course of the annual medical examination by the school physician, was told that her tonsils were infected This young woman consulted me on August 19 and the history and findings were as follows

History The patient had had diphtheria eight years ago, and had made an uneventful recovery, following the administration of antitoxin From that time she complained of several attacks of "sore throat" Her appetite had been poor and her general health only fair, she tired much more easily on exertion than her classmates

Clinical Examination The general appearance was that of a fairly well developed but slightly undernourished girl Her mucous membranes were pale The tonsils were small, embedded and cryptic Spreading on the surface of the tonsils and pillars was a dense greyish white mucoid material which extended downward and to the posterior wall of the pharynx It could be removed only with forceps and was found to be very tenacious

Bacteriological Examination Both morphological and cultural examinations were made of the material recovered from the tonsils and pharynx Stained and moist unstained preparations with 25 per cent sodium hydroxide were examined, and morphologically typical diphtheria bacilli and oval refractile, budding yeast-like organisms were found A few mycelia were noted also Material was collected on Loeffler's coagulated blood serum medium and incubated at 37°C A diphtheria bacillus, which proved to be nonvirulent and a yeast like organism were isolated Further study of the morphology of this organism, as well as a determination of the biochemical characteristics, as outlined by Castellani[1] proved it to be *Monilia krusei*

Castellani[2] has reported several cases of tonsillitis in which the incitants were fungi, among them *Monilia krusei*, but no record has been found of the isolation of two such organisms from the same case

Treatment Electrodesiccation was chosen as the method of treatment since it offered the possibilities of sterilization and the removal of the tonsils at the same time This was obtained by the use of a high frequency current varying from 250,000 to 400,000 cycles per second One tonsil was treated at a time and the treatments were given at weekly intervals Cultural tests were made after each fulguration Each tonsil was completely removed on completion of the third treatment and no diphtheria bacilli were isolated thereafter The fungus still persisted, however, on the posterior surface of the anterior pillar and on the posterior wall of the pharynx The remaining treatments were directed toward the destruction of the fungus and this was accomplished following the ninth Several cultures taken after the final electrodesiccation showed no growth of diphtheria bacilli on Loeffler's medium nor of the fungus from material collected on Sabouraud's medium and incubated for seven days The treatments caused little inconvenience and the patient was able to attend her daily classes

Summary Tonsils harboring *Monilia krusei* and a nonvirulent strain of diphtheria bacilli were removed by electrodesiccation Cultural tests indicated that the organisms were eliminated during the course of treatment which lasted nine weeks

The continued presence of these organisms after each electrodesiccation which did remove a superficial layer of tissue showed that they were not merely adherent to the surface of the tonsil but had invaded the submucosa This observation together with the history of many attacks of "sore throat" indicated that these organisms did not exist merely in the state of harmless parasitism

CONGENITAL HEARTS AT AUTOPSY

By PAUL COHEN, M.D., NEW YORK, N. Y.
From Strecker Laboratory, City Hospital, Welfare Island, N. Y.

DURING the past four years at City Hospital we have met with about one dozen congenital hearts out of nearly one thousand autopsies. Of these we desire to report eight cases.

The age incidence is noted in the following table:

Case No.	Age	No. of Cases
1 and 2	2 days	2
3	3 weeks	1
4	4 "	1
5	5 years	1
6	20 "	1
7	31 "	1
8	57 "	1

Of these, Cases 1 and 3 were found to present the usual common findings, viz.—large patent foramen ovale and patent ductus arteriosus;

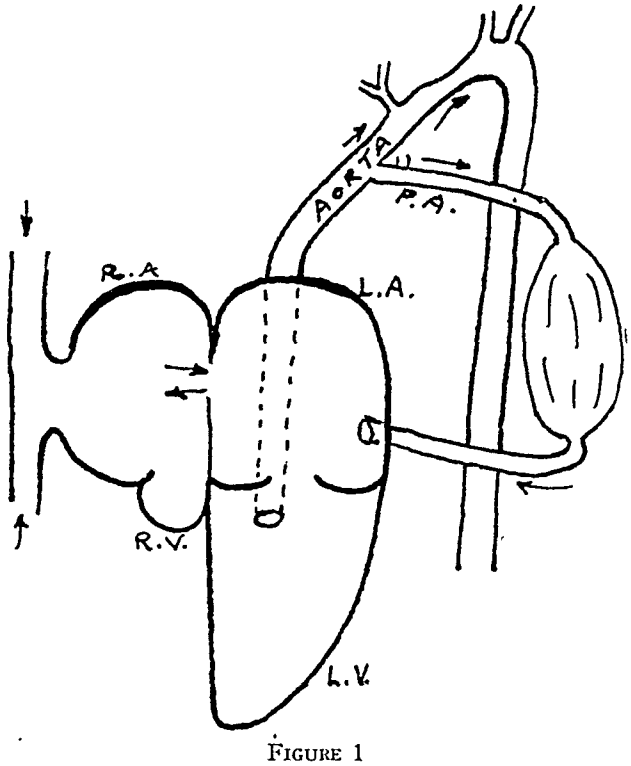

FIGURE 1

Case 2—Trilocular Heart with the pulmonary artery as a branch of the arch of the aorta.

the latter in Case 3 arising at the bifurcation of the pulmonary artery.

Case 4 presents in addition to the above findings, a defect in the upper part of the interventricular septum.

Case 8 is of interest only in the presence of a patent foramen ovale, although the patient died of rheumatic endocarditis at the age of 57.

The four remaining cases are of greater interest and will be presented in greater detail. See diagrammatic sketches.

Case 2 presents the pulmonary artery as a branch of the arch of the aorta. The right ventricle is ¼ inch in diameter. The foramen ovale is patent.

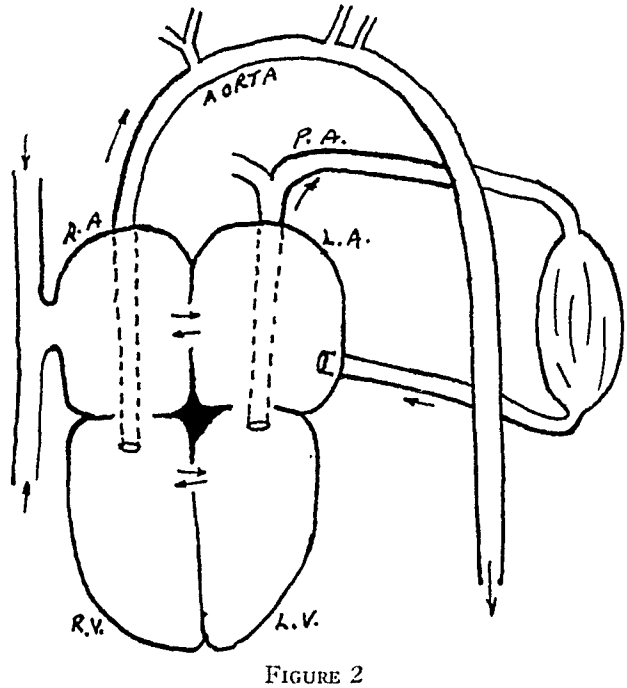

FIGURE 2

Case 5—Four-chambered Heart with defective septa and transposition of the aorta and pulmonary artery.

Case 5 shows the aorta coming from the right ventricle while the pulmonary artery empties the left ventricle. In addition the interventricular septum shows a defect and the foramen ovale is patent. Clinically this case, a boy, showed marked cyanosis and clubbing of the fingers and toes. There was a blowing systolic murmur heard over the precordium, but loudest over the pulmonic area. The liver and spleen were palpable; R. B. C. 7,800,000; Hbg. 120.

Case 7 shows the aorta arising from both right and left ventricles, the pulmonary artery arising from the right ventricle behind. The level of the pulmonary cusps is 5 cm. above the mouth of the artery, the intima above being lace-like in character, and the walls of the artery very thin. The great vessels of the neck are transposed. The interventricular septum has a defect in the upper portion. Clinically this case was a blue baby. Vegetations were found on the mitral valves.

Case 6. The heart is very large and globular, weighing 400 grams. The right ventricle is very large and comprises most of the heart. The aorta arises from the right ventricle. Both inferior and superior venae cavae open into the left auricle which lies behind the right auricle. The foramen ovale is patent, the ductus arteriosus is closed, the aorta has three

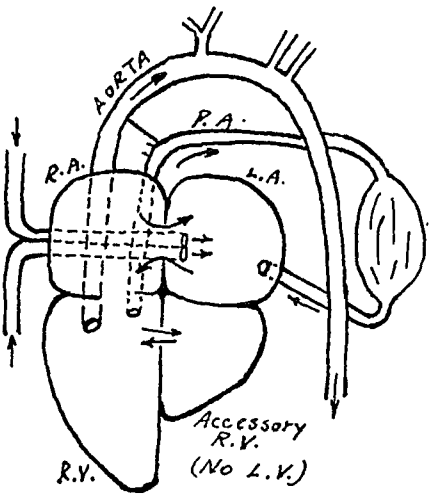

FIGURE 3
Case 6—Triloculai Heart with accessory right ventricle and anomalous origins of aorta and vena cavae.

There is a small accessory chamber immediately beneath the anterior portion of the aorta and communicates with the large right ventricle by a large opening. Posterior to the aorta is the opening of the pulmonary artery.

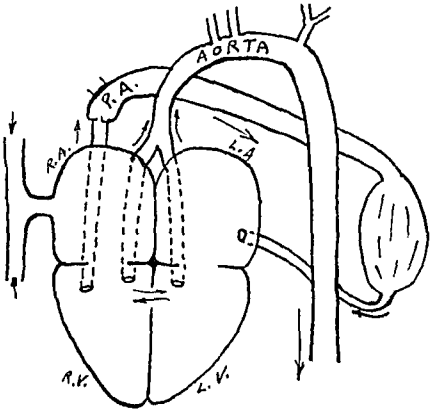

FIGURE 4
Case 7—Four-chambered Heart with defective septum anomalous pulmonary artery, double origin of aorta with transposition of vessels arising from aortic arch.

cusps, the pulmonary artery has two cusps. Clinically, the patient showed cyanosis and clubbed fingers and toes. There was a diffuse apical impulse, and a diffuse systolic thrill at the apex and in the left second space. Death followed pulmonary infarction secondary to thrombosis of the left femoral vein. Tuberculosis of the lungs was disclosed at autopsy.

COMMON DERMATOSES OF THE FACE

By IDA J. MINTZER, M.D., JAMAICA, N. Y.

From the Dermatological Department of the New York Post Graduate Medical School and Hospital, George M. MacKee, Director. Read before the Medical Society of the County of Queens, Forest Hills, New York, Feb. 24th, 1931.

THE purpose of this presentation is to consider the various methods of treatment that may be used in some of the more common dermatoses of the face, rather than to discuss the etiological factors. Many of these skin diseases are amenable to any one of several agents or their combinations. The subject will be considered under the following headings:

Anomaly of pigment as Freckles, Chloasma.

Anomaly of hair Development as Hypertrichosis.

Constitutional unbalance with local manifestations as Acne Vulgaris, Rosacea, Eczema.

Infections caused by

1. Pus organisms, as in Erysipelas, Impetigo Contagiosum, Sycosis Vulgaris.
2. Fungi, as in Tinea Barbae.

Dermatitis Venenata caused by plants and chemicals.

Constitutional or local infections as Syphilis, Lupus Vulgaris, Lupus Erythematosus.

New growths as Molluscum Contagiosum, Nevi, Epitheliomas

FRECKLES: Circumscribed collections of pigment, the size of a pinhead or larger. Freckles usually do not make their appearance before the sixth or eighth year, and may persist throughout life, being exaggerated each summer. The treatment consists of peeling the epidermis. Bichloride of mercury applied as a lotion in the strength of one half to four grains to the ounce of water or alcohol, dabbed on two or three times a day is of benefit. Hardaway (1) touches each freckle with a needle connected to the negative pole of the galvanic battery.

CHLOASMA: A condition that frequently occurs in women, especially during pregnancy and at the menopause, and is likewise seen in other derangements of the reproductive organs. When the disease is due to some systemic or internal disorder, it is likely to improve or disappear when health is regained. Sometimes the use of glandular products, especially whole ovary, are of value. The local treatment consists in peeling the epidermis with lotions containing salicycle acid or bichloride of mercury, or letting strong soaps stay on the patch all night in the form of a plaster. When the latter is used it is washed off in the morning and cleansed with carbon tetrachloride 5 per cent in alcohol, followed by a lotion containing bichloride of mercury 1:1000, or salicylic acid, 2 per cent in alcohol. Andrews (2). When the irritation causes discomfort, use cold cream until the reaction subsides.

HYPERTRICHOSIS: An increased hair growth in regions normally occupied by lanugo hairs. The hypertrichosis considered here is that which occurs on the bearded portions on the faces of females. At the onset epilation or irritants should not be employed. The plainly visible downy hair may be bleached with strong solutions of hydrogen peroxide. When the hairs are large, electrolysis is the only safe treatment. Eller and Satenstein (3). Radiotherapy should never be used because of the possible sequelae of radiation.

ACNE VULGARIS: Is characterized by a set of polymorphous lesions, such as comedones, papulopustules, superficial or deep follicular pustules, crusts and cicatrices. In most cases there is an associated seborrhoea. The disease usually occurs on the face and back of adolescents. The treatment should be constitutional as well as local. Fats and carbohydrates should be reduced in the diet, and water taken freely between meals. Bitter tonics, dilute hydrochloric acid and pepsin, and liver extract in the anemic, R. L. Sutton (4), are all of service. Pathological conditions in the intestinal tract or in other organs should be corrected, and attention paid to the general hygiene of the patient. Locally, the patient should be advised against the use of greasy creams. Comedones must be expressed and pustules evacuated. Of the remedial agents, sulphur 2 to 8 per cent is the best, and may be used in the form of an ointment or lotion. One of the most valuable methods of treatment, is to stimulate the sluggish skin until a mild dermatitis is produced. This is accomplished by washing the face with tincture of green soap and hot water for three or four successive nights, and applying an ointment containing sulphur or resorcin, 5 to 60 grains to the ounce of lanolin or cold cream. When reaction occurs stop treatment and apply soothing applications as zinc oxide in liquor calcis, or calamine lotion. The treatment is resumed when the reaction subsides., until after a number of courses, the desired effects are obtained. Andrews (5). Roentgenotherapy in acne, gives excellent results. MacKee (6), J. C. Michael (7). It should be used according to the MacKee standard, one quarter skin units, unfiltered, once a week, and with few exceptions, sixteen weekly treatments should not be exceeded. All indolent cases, accompanied by an oily seborrhoea, deep seated destructive lesions or hypertrophic scarring, are greatly benefited by *x*-rays. Ultra-violet light is useful, especially where the affection is superficial, acutely inflamed, and no notable comedones; but recurrences are the rule, and so far no other form of treatment has given the good and fairly rapid results obtained by the *x*-rays. Vaccines and bacteriophage, D'Herelle (8), in pustular acne is said to be of value.

ROSACEA: A chronic disorder of the skin of the nose and the flush areas of the face, characterized by congestion, acneiform lesions, telangiectasis, and if the condition persists, hypertrophy of the skin of the nose. Rosacea may occur alone or be superimposed upon a persistent acne vulgaris. The treatment here too should be constitutional as well as local. Highly spiced food, hot tea and coffee, and hot soups should be avoided. Bowels should be regulated and digestive disturbances corrected. Locally, lotio alba is effective in all stages of the disease. The dilated venules may be treated by electrolysis, which is the method of choice, scarification or electrodesiccation. Distance application of ultra-violet light twice weekly, with first and second degree reactions are beneficial. *X*-rays are of some benefit. In the third or rhinophyma stage, the early lesions can be cured by bipolar endothermy. Each nodule or enlarged sebacious gland is penetrated with the needle, and the current is then turned on for the time necessary for coagulation. After several treatments, the nodules contract and the nose gradually returns to normal. Eller (9). At this stage fractional doses of unfiltered *x*-rays given weekly, for several weeks may prevent a recurrence. In the more advanced cases surgical endothermy is an ideal method of treatment, though a sharp scalpel may be used to remove the redundant tissue.

ECZEMA: The most common type observed is the erythematous variety. The skin is infiltrated, dusky red. The forehead, cheeks, eyelids and nose are most commonly affected. This type may progress to other phases of the disease in which the skin is crusted and exudative. The treatment during the acute stage should consist of local applications of soothing oils and creams, until the acuteness subsides, and in addition it is desirable to apply subfractional doses of *x*-rays to each cheek and occasionally to the forehead. After the acute stage has passed, roentgen therapy becomes of increasing importance for the control of the squamous infiltrated lesions of chronic facial eczema.

ERYSIPELAS: An acute streptococcus infection of the skin and subcutaneous tissues. The constitutional treatment of erysipelas is largely symptomatic. Rest in bed together with a simple nutritious and easily assimilated diet is essential. Locally, constant wet dressings of boric acid solution, or saturated solution of magnesium sulphate, or aluminum acetate, etc., is soothing to the patient at first, though later may cause discomfort. Ichthyol in ointments or in aqueous solution, 10 to 25 per cent is very popular. Solutions of phenol, iodine, silver nitrate, etc., have been variously used in attempts to stop the spreading of the disease, but frequently did more harm than good on account of their irritating qualities. Since the advent of effective erysipelas antitoxic sera, all other methods of treatment in the acute stages of the disease have become of secondary importance; and likewise, injections of streptococcus erysipelatis toxin, may be used for the prevention of recurrences in cases of chronic recurrent erysipelas. In the latter cases focal infections should be sought for in the sinuses, teeth and tonsils.

IMPETIGO CONTAGIOSA: A contagious disease which may occur at any age, but is most common in children. The treatment of this disease is comparatively simple. All that is necessary is strict cleanliness with soap and water, open pustules when present, remove the crusts, and the application of ammoniated mercury 3 to 10 per cent, or sulphur ointment in the same strength, 2 or 3 times daily. In the stubborn cases ¼ or ½ skin units of unfiltered *x*-rays, frequently hastens the cure. *X*-ray treatment is particularly useful in adult males, where the disease is recalcitrant because of the beard. Andrews (10).

SYCOSIS OF THE BEARD: There are two types; tinea barbae, which is a fungus infection, and sycosis vulgaris, which is a bacterial infection of the hair follicles of the bearded region, and occasionally of other hairy regions. Sycosis vulgaris may be the simplest or the most difficult disease to cure. In some patients rapid involution is caused by a 10 per cent ammoniated mercury ointment, without even manual epilation, whereas in others, permanent alopecia established by *x*-rays, together with all kinds of local antiseptics and vaccines, fail to result in a cure. The treatment in the acute stage should consist of hot applications of boric acid solution, applied several times daily, with a soothing ointment between applications. When the acuteness subsides, hot bichloride of mercury dressings, 1-2000, and ammoniated mercury ointment may be substituted. *X*-ray is a most valuable form of treatment to be used as an adjunct to the above measures, though sometimes the disease develops a tolerance to *x*-rays after 8 or 10 such treatments in which case the exposures must be increased to produce a temporary alopecia, and in very stubborn cases, nothing short of a permanent alopecia will help.

TINEA SYCOSIS is not a common disease. No other single remedy is as effective in this disease as *x*-rays.

DERMATITIS VENENATA: May be caused by various substances of animal, vegetable and chemical nature, in persons of known susceptibility. A common cause of acute dermatitis about the forehead, eyes, face and neck is found in proprietary hair dyes and in furs, and also in the analin dyes found in the face powders and rouge. The treatment in the acute stage when edema and vesiculation are present, is soothing wet dressings. This may be changed to astringent preparations, as carbolated or mentholated calamine lotion when the acute symptoms subside. In the case of dermatitis caused by poison ivy, the patient may be immunized with small doses of rhus toxicodendron during the poison ivy season. Schamberg (11). In all cases the recognition of the irritant, and the avoidance of coming in contact with it is essential.

LUPUS VULGARIS: This is a true tuberculosis of the skin, which in the majority of cases begins in early life. Under pressure with the diascope, the inherent brown color of the individual nodules of which the patch is composed is seen. This peculiarity is characteristic and important in diagnosis. Lupus vulgaris is a difficult disease to clear up. The systemic treatment is of great importance, and the rules laid down for the management of tuberculous patients, apply to those suffering with the disease located in the skin. This should consist of generalized ultra-violet light baths, cod liver oil, nutritious food, rest and out-door life. Tuberculin given over a long period of time is of value. Salt poor and high vitamine diet is reported to give excellent results. Gold injections have also given good results in the hands of some clinicians. Locally, complete destruction of the diseased patch by electrodesiccation and thorough curettment,

followed by ultra-violet is probably the most effective treatment. When the involved areas are larger or accompanied by ulceration and hypertrophic scarring the cutting current is more suitable, though the cosmetic results are not so good. Kromayer light applied to the affected patch in sufficient dosage to produce an intense local reaction, has cured a small percentage of cases. Refrigeration by carbon dioxide snow, requires repeated treatments to bring about results. The reaction and pain are severe. The results that are reported from the use of the finsen light used in the Finsen Institute at Copenhagen and other European centers, cannot be duplicated anywhere else in the world. In certain cases results can be obtained with radiotherapy, but the untoward results, as atrophy and telangiectasia are so common, that it is inadvisable to use this form of treatment, if other measures can be employed.

LUPUS ERYTHEMATOSUS: This is a chronic, for a short time inflammatory process terminating in atrophy. The disease consists of erythematous infiltrated patches covered by adherent scales. These plaques spread at the periphery and heal in the center with atrophy, scarring and telangiectasis. It most frequently occurs in young adults on the bridge of the nose and flush areas of the cheeks, in the form likened to a butterfly. The treatment of lupus erythematosus has been more successful in the last few years, since the addition of the various gold preparations to our therapeutic realm. Gold and sodium thyosulphate is the most stable and least toxic preparation. Schamberg and Wright (12). The compound is injected intravenously every 5 or 10 days over a considerable period of time. This compound is now used locally with considerable success. Locally, in the acute cases, soothing wet dressings followed by lotio alba is beneficial. After the acuteness subsides topical applications of salicylic acid 5 to 20 per cent in alcohol, painted on the lesions 2 or 3 times daily, until considerable peeling is induced. These applications are renewed after the subsidence of each reaction, until after a number of courses the infiltration disappears. Carbon dioxide snow gives good results, both from a curative and cosmetic standpoint. Eller (13). Radium and *x*-rays should not be used because of the possible radiodermatitis and its sequelae.

SYPHILIS: Chancre, maculo-papular and gummatous lesions are not uncommon on the face. The disease should be investigated and the treatment is the same as for similar stages of the disease on any other part of the body.

MOLLUSCUM CONTAGIOSUM: An infectious type of epithelial overgrowth, consisting of one or more papules, with a central depression, from which a caseous plug, called the molluscum body, may be squeezed. It most commonly occurs in children. The condition is treated simply by the manual expression of the molluscum body from each individual lesion, and by applying carbolic acid to the central cavity with a toothpick, or the lesions may be treated by curettage, followed by painting the bases with carbolic acid or iodine. Healing occurs within a week, leaving no scar.

VERRUCA PLANA JUVENILIS: Occurring on the face is often mistaken for lichen planus. This variety of warts can readily be treated by desiccation without any anesthesia, using a small cold spark. The dried-up warts are then removed with a dull curet, and the bases painted with tincture of iodine. Daily painting with a salicylic acid in collodion, 1 to 8, or rubbing with an ointment containing 5 per cent of both salicylic acid and resorcin is generally successful. The internal administration of mercurous iodide, one-sixth or one-quarter grains three times daily has proven successful. H. Fox (14), C. T. White (15). The various arsphenamine injections seem effective in some cases.

NEVUS FLAMMEUS: Portwine marks vary in size and color and are never elevated above the surface of the skin. The best treatment for this condition is carbon dioxide snow. With small doses applied frequently, very excellent results can be obtained with a minimum of scarring. Using Dr. Lorıat Jacob's (16) apparatus, the pressure is accurately controlled by a spring gauge. Many authorities advocate the compression technic with the Kromayer light, though equally good results follow distance radiation with the air-cooled ultra-violet light. With either compression or distance therapy, blistering doses are necessary, and should be repeated at frequent intervals before the erythema of the preceding treatment subsides. *X*-rays and radium therapy should not be used in the treatment of this condition, MacKee (17), because of the unsightly scarring and the possible sequelae of radiation.

ANGIOMA CAVERNOSUM: In this type of vascular nevus the deep vessels, especially the deep veins, are involved. The lesions appear at or shortly after birth, are round or irregular in contour, and are elevated in varying degrees above the surface of the skin. Occasionally the condition undergoes a slow spontaneous fibrosis or is cured as a result of accidental traumatism, but this often results in more scar formation than when treated with radium, from which remarkable results are obtained. There are various other methods of treating these lesions, such as, refrigeration with carbon dioxide snow, *x*-rays, bipolar endothermy or general surgical procedures. Radium, however, gives such good results that it is the method of choice.

FLESHY, PEDUNCULATED SOFT MOLES Flaccid appendages sparsely pigmented and usually nonhairy These lesions may be removed without hazard by grasping the mole with a pair of forceps, freezing it with ethyl chloride, and clipping it from the base with a pair of small scissors The larger moles may be removed by a scalpel under local anesthetic

NEVUS PILOSUS These nevi may or may not be pigmented In all hairy nevi the hairs should first be removed by electrolysis, which often results in obliteration of the lesion The larger moles may be removed by transfixing the lesion in several directions with the needle attached to the negative pole, using a current of 2 or 3 ma

BLACK OR BLUISH BLACK MOLES These are the most dangerous type of nevi from the standpoint of malignancy They are generally nonhairy and vary in degree of elevation It almost always is a dormant melanotic cancer and should be left untreated unless it shows some evidence of increase in size or deepening of pigment, or if it is exposed to irritation from friction The treatment should be most radical, for any palliative measures may result in general metastasis and death The best method is to remove the lesion intact with the high frequency cutting current, circling wide for one-half or three quarter inches out from the lesion, Radium is then applied to the original site of the lesion, and to the surrounding area, as well as heavy doses of filtered *x*-rays to the glands which drain the affected site The endotherm knife is preferable to the ordinary surgical incision in that the lymphatics and capillaries are sealed by the heat of the current simultaneously with the removal, thus lessening the chance of metastasis

BASAL CELL EPITHELIOMA These lesions develop slowly, are relatively benign and do not metastasize If left untreated it acts as a rodent ulcer leading to mutilation, and if in the vicinity of the nose or eye, which is a frequent location, it will destroy the cartilage or the eye In treating basal cell epitheliomas, a variety of methods may be used, such as *x*-rays, radium, electrocoagulation or surgical excision Results can only be obtained if all the cancer cells are destroyed Electrocoagulation and curettment is an ideal procedure It is not only a rapid but thoroughly destructive method and leaves a minimum of scarring Irradiation also gives excellent results with a minimum of scarring and perfect cosmetic results, with no pain or shock to the patient MacKee (18)

PRICKLE CELL EPITHELIOMA This presents a more difficult problem than the basal cell type It is malignant and has a tendency to metastasize early The most common location is the lower lip, and occurs more often in men past forty The malignant neoplasms may be preceded by single keratosis, though there are occasionally multiple foci This type of cancer must always be treated in the most radical way for a cure Surgical removal with the endotherm knife, followed by radium to the primary site and heavy doses of filtered *x*-rays to the glands which drain the affected area, give the best results MacKee (19) *X*-ray or radium alone may cure skin cancers, and have an advantage over surgery because of the better cosmetic results, but the combination of surgical removal with irradiation give the greater percentage of cures

HOW CANCER PATIENTS ARE TAKEN CARE OF BY THE CITY OF NEW YORK*

By IRA I. KAPLAN, M.D., NEW YORK, N. Y.

From the Division of Cancer, Department of Hospitals, City of New York, Dr. J. G. Wm. Greff, Commissioner. * Delivered over Radio Station WNYC, April 15, 1931.

EVER since early civilization the state has assumed the burden of caring for the health of its citizens. The diagnosis of a disease and the application of some curative measure by no means sums up what is required in caring for the sick, especially for those suffering from cancer. The more obscure the causes and the cure of a disease, so much the more interested in its study must the state necessarily be. For this reason it is that the increasing ravages on life, due to cancer, have compelled the people to look to the state for protection.

New York City has accepted this responsibility by establishing a Division of Cancer in the Department of Hospitals. This Division concerns itself with the diagnosis, treatment and care of cancer patients applying to the municipal hospitals for help.

First, it provides proper care for those, who, due to economic conditions beyond their control, are unable to care for themselves. Secondly, it offers its patients the most up-to-date treatment with those curative means which have proven of value in the campaign on cancer. Thirdly, it possesses a broad educational aspect for both the lay and the professional public. And fourthly, it offers a wonderful teaching medium for enhancing the efforts of the physicians of the City to control the disease.

Unfortunately, cancer has from time immemorial been considered a loathsome disease that subjects the victims to an ostracism more deadly than the malady itself. Thanks, however, to a more enlightened era of public education, people are becoming more sensible towards the sufferer from cancer, and as this disease is (as far as we know) neither contagious nor infectious, the cancer sufferer need no longer be assigned to the meanest quarters of the home. As far as we know, cancer in the human being is not hereditary, therefore, families need not have any fear on this account if one of their members is a cancer victim.

Cancer patients are divided into three groups: the incipient or early case, the chronic, and the advanced or hopeless case. It is with the incipient early case that medicine can do the most; a great deal can be done for the chronic patient to ameliorate his condition; while the hopeless can only be helped to pass away with a minimum amount of torture and suffering.

Although the cause of cancer is still unknown, we have learned by observation and experience that up to the present time the most effective treatment is given by surgery, *x*-ray or radium, or a combination of all these methods. Positive cure in cancer depends on two factors—an early diagnosis and prompt appropriate treatment.

Patients come from several sources to the units established by the Cancer Division. They may come directly through some fear, or sudden discovery of a growth, or following some cancer educational campaign. They may be referred by the wards of the hospital wherein the cancer unit is established, or by outside clinics and hospitals, or the family physician.

When a patient first comes to the cancer unit he is thoroughly examined and every scientific means necessary is made use of to establish the diagnosis of his condition. When the diagnosis is made he is given the proper advice as to treatment, and if he accepts this advice such treatment is carried out. Due to close association between the cancer units and the general hospital, the service of the staffs is available to these patients so that they may receive the best surgical and medical care in addition to the most up-to-date radiation treatment that their individual condition may require.

To be effective, though, the treatment of cancer must be instituted early. Therefore, the patient who comes to the cancer clinic early stands the best chance to be cured.

How are we to know cancer? Not all abnormal conditions are cancerous, but it is better to be skeptical and get a physician's advice and find the condition to be a harmless one than to wait until the disease is rampant throughout the body. Any abnormal growth appearing anywhere on the body, which persists in growing or ulcerates, should receive attention. Any long-persisting sore on the lip, tongue or mucous membrane of the mouth, and abnormal lumps or tumors appearing on the body, in the breasts, on the side of the neck, or in the armpits, should be reason enough for medical examination. Any interference with normal body functions, such as abnormal menstrual activity, persistent constipation (especially with bloody stools), persistent heartburn, and bloody vomiting require immediate medical consultation.

By taking care of early abnormal conditions, cancer development can be arrested or prevented.

The Division of Cancer already has established several units and others are being

created for carrying on this work. To take care of many unfortunate men and women suffering from cancer who find themselves in a desperate predicament due to economic and social conditions over which they have no control, there is a Cancer Social Service attached to the Division of Cancer. This Social Service sees to it that the patient comes regularly to the clinic for treatment and observation, takes care of the social and economic needs of himself and his family, and, by preventing the loss of his job, keeps his family from suffering hardships while he is being cared for medically. It looks after the spiritual and mental happiness of those to whom can be given only custodial care in an institution for hopeless cases.

The units already established for cancer work are the Radiation Therapy Department at Bellevue Hospital, 26th Street and First Avenue; the Cancer Clinic, 124 East 59th Street; the Brooklyn Cancer Hospital, 109 Cumberland Street, Brooklyn; and the Custodial Cancer Hospital on Welfare Island.

In the near future, the new Radiation Unit at Lincoln Hospital, East 141st Street and Southern Boulevard, Bronx, will be opened for the care of cancer patients.

The Cancer Division is always on the lookout for a real cancer cure and is constantly testing out proposed remedies, but both the public and the physician are warned against quacks and pseudo-specialists who attempt to treat patients with secret remedies or insufficient quantities of radium. It is essential that the patient go to ethical, well-trained physicians for advice, or, when economic conditions require it, come to legitimate cancer clinics, such as those of the Department of Hospitals, for proper advice and treatment.

Cancer does not always have to be treated in hospitals. In many instances the condition can be treated while the patients remain ambulatory; that is to say, the patients can come and go from their homes for the necessary treatment. But the patients must remain under observation even after the local condition is controlled.

The public should not try advertised cancer cures because in this way they may delay proper treatment until it is too late. Anyone who feels the slightest suspicion that he is developing cancer should immediately secure advice from a competent physician or directly from the City's cancer service.

As I said at the beginning of this talk, New York City—through the Cancer Division of the Department of Hospitals—is doing all in its power to check the ravages of this dread disease. It offers cancer victims every known facility for the amelioration of their condition. It seeks to educate the public as to the severity of cancer's menace and to teach the physicians of the City the most modern methods of coping with the disease. It undertakes research in the hope of discovering the cause of cancer and bringing to light an adequate cure.

But the City's efforts can meet with success only if the public becomes thoroughly awakened to the significance of this very real health hazard and takes steps to bring to immediate and scientific treatment all suspected cases.

DECAPSULATION OF THE EPIDIDYMIS

By MAURICE MELTZER, M.D., NEW YORK, N. Y.
From the Department of Urology, Broad Street Hospital, New York.

THE purpose of this presentation is to introduce a new and modified technique of Hagner's operation. Decapsulation of the epididymis has been practiced by the author for three years and he is convinced that, in acute epididymitis, the procedure is an improvement and more rational than epididymotomy.

The treatment of acute epididymitis, most commonly secondary to gonorrheal infection, is quite standardized. As soon as this complication occurs, all local treatment is discontinued. The patient is placed in bed and the following routine usually is employed: elevation of the scrotum, application of an ice-bag to the affected region, hot rectal irrigations for the coexisting prostatitis and seminal vesiculitis, bland diet, forced fluids, attention to intestinal elimination, appropriate medication for pain and temperature, intramuscular injection of Aolan (milk) to induce protein reaction, or intravenous injection of mercurochrome or sodium iodide combinations. The palliative measures, separately or combined, usually result in subsidance of the acute congestion and mild inflammatory process in the epididymis.

Palliation usually is seen within a week. *In many instances, despite faithful application of palliative measures, the inflammatory process persists and small punctate abscesses form in the epididymis, some of which coalesce to form a localized conglomerate abscess or multiple abscesses.*

Any part of the epididymis may be affected. Clinically, progression of the inflammation with abscess formation is recognized by continued and often increased local pain and tenderness. Absorption from the suppurative focus results in chills, fever and general malaise. This combination of local and general symptoms, when unrelieved by palliative treatment, is Nature's way of calling attention to the necessity for drainage. Surgical drainage rather dramatically and quickly terminates the patient's invalidism. Some prefer continuance of palliative treatment, but experience has shown the fallacy of such judgment, because the patient's return to normalcy is unduly prolonged. From an economic standpoint, surgical drainage is not only desirable but the surest and most rapid way of restoring the patient to his usual vocation.

Surgical treatment for acute epididymitis is that described by Hagner in 1902. The operation is designated as "Epididymotomy."

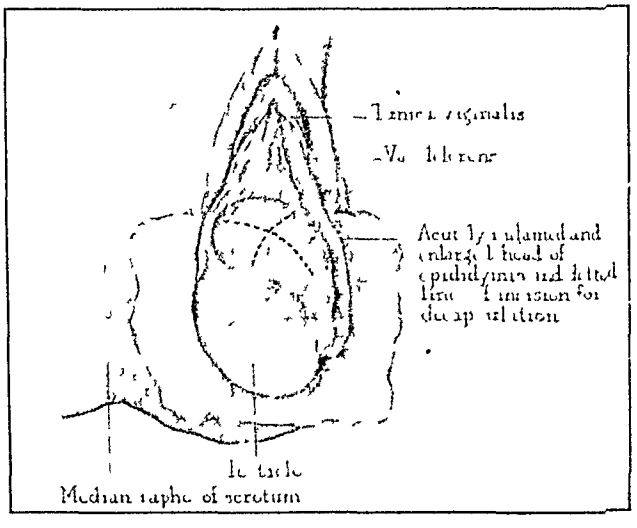

ILLUSTRATION 1

The well-known technique of epididymotomy is here described to bring out the limitations of mere puncture of the epididymis:

A dorsal incision is made on the affected scrotum, the tunica vaginalis sac and contents freed and delivered. The tunica sac is opened, releasing a varying amount of coexisting inflammatory hydrocele fluid; the tunica vaginalis usually is excised to its neck along the spermatic cord and the cut edges sutured. The tumefied and tense epididymis is now exposed. The usual procedure is to make multiple punctures with a Hagedorn needle. Extravasations of blood or droplets of pus ooze through these openings. The tumid area is thoroughly punctured and extra punctures usually are made in regions where pus is found. All bleeding points are securely tied, the testicle replaced in normal anatomic relations and the scrotal sac closed with drainage.

Epididymotomy usually is followed by cessation of symptoms in a few days and the patient is out of bed in about one week. In the writer's experience, however, some patients have had acute recurrences and were confined to bed for a longer period. *It therefore seemed reasonable to infer that continued pain or recurrence of symptoms most likely was due to tension and faulty drainage of pus, retained by the acutely inflamed fibrous capsule of the epididymis.*

About three years ago, with this thought in mind, the writer in the course of an epididymotomy incised and stripped back the capsule. The technique is analogous to renal decapsulation. Decortication not only suspends all tension upon the swollen epididymis, but also exposes any abscess foci. Decapsulation, rather than simple epididymotomy, has been practiced by the writer ever since. No recurrences have been noted and relief of symptoms is quicker. Careful search of the literature reveals this to be the first description of any attempt to visualize and facilitate drainage of pus in the epididymis.

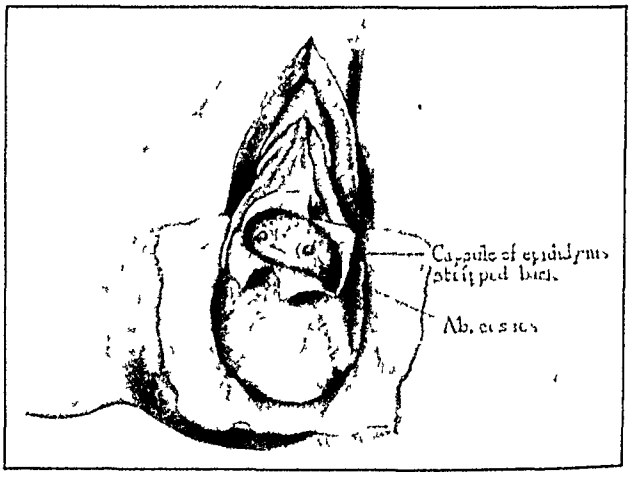

ILLUSTRATION 2

Decapsulation of the epididymis makes a more surgical procedure of Hagner's operation. *Not only does decortication immediately remove tension upon the acutely swollen tubules of the epididymis, but stripping-back of the capsule also reveals any abscess areas.* These readily can be probed and drained and topical applications of mercurochrome, hexylresorcinol or metaphen made to them.

AUSCULTATION OF THE ABDOMEN IN THE DIAGNOSIS OF HYPERMOTILITY

By NEIL C. STEVENS, M.D., GLEN COVE, N. Y.

AUSCULTATION of the abdomen is a valuable method of diagnosing hypermotility of the stomach and intestinal tract and is an aid in the differential diagnosis of a few other intestinal conditions. Although it is so simple and so instructive, the writer has never seen it employed by any physician or surgeon nor heard of it being taught in any medical school. Its chief value is in determining the presence or absence of hypermotility.

Hypermotility is a very common condition. It is often noted in fluoroscopic and x-ray examinations, but owing to the comparatively small number of cases x-rayed, it has not received the consideration it deserves.

Hypermotility is one of the commonest causes of indigestion. It can cause discomfort, gas, pain, nausea, heartburn etc. Most commonly it is associated with rather frequent bowel movements, i. e., two or three a day. Sometimes the hypermotility is so pronounced that it causes a spasmodic condition of the intestine with resulting constipation. These cases are usually treated by cathartics and colon irrigations which tend to increase the hypermotility and spasm.

The causes of hypermotility are organic, such as, peptic ulcer, cholecystitis gallstones, chronic appendicitis, and adhesions, and functional due either to nervousness or fatigue.

Hypermotility that does not cease in a few days after the administration of sedative drugs is in all probability due to an organic and not a functional cause. Duodenal ulcer and chronic appendicitis are common causes. Post-operative adhesions are a frequent incitant to spasm and hypermotility.

Most cases of acute abdominal distress of functional origin, if not due to constipation and hyperacidity, are caused by hypermotility. Functional hypermotility begins most commonly in the third decade at a time when individuals are subjected to the unaccustomed stress and strain of existence. Many cases begin after a period of prolonged fatigue or nervous tension. It is a common condition among stockbrokers. It seems to be associated quite often with over-indulgence in alcohol. Sea-sickness is an illustration of an extreme degree of hypermotility.

Functional hypermotility can simulate a number of acute abdominal conditions, and in some cases it is of importance to know whether increased peristalsis is present or absent. In the beginning of an acute appendicitis there is pain, tenderness, slight or marked rigidity in the right lower quadrant, nausea; there may be a slight rise in temperature and pulse rate. In many cases of acute indigestion there is pain in the right lower quadrant, tenderness, distension which may simulate rigidity, nausea and vomiting. The temperature may be slightly elevated. Perhaps we see the case in the middle of the night when it is not easy to have a blood count done. Shall we let the case go till morning or shall we advise immediate removal to the hospital?

Very often the presence or absence of hypermotility will decide the question for us. Nature makes every effort to protect an inflamed appendix. She quickly draws the omentum over and around it; she throws the muscles of the abdominal wall into spasm to secure as much protection as possible and she slows down the peristaltic action of the intestine, so as not to further traumatize the inflamed organ. So in the large majority of cases of acute appendicitis hypermotility is absent. If it is present we may feel reasonably sure that we are dealing with a case of indigestion.

Diagnosis. If one listens with a stethoscope at an arbitrary point of the abdomen—one inch to the right and one inch above the umbilicus, one will hear from three to six faint gurgles or tinkles per minute in the normal individual. The number of tinkles may vary somewhat according to the temperament of the individual and according to the time of day. Peristalsis naturally is more active for an hour or two after meals. But the normal stomach or intestine never emits loud, harsh or prolonged gurgles. To one who has accustomed himself to this method, the distinction between normal and abnormal sounds is marked and easy of recognition. In some cases of marked functional disturbance the gurgle is loud, continuous and apparently never ceases. Sounds heard over the stomach are of higher pitch than those heard over the intestine. Sounds heard over the epigastrium, unless very loud, are not audible in the right or left lower quadrant and vice-versa.

CASES

Case 1—School boy aged 9. Apparently healthy, somewhat nervous and slightly underweight. Subject to periodic and violent attacks of indigestion, simulating appendicitis. In one attack narrowly escaped operation. X-ray of intestinal tract revealed a transposition of intestines. No note was made of hypermotility. Weight at the time of X-ray 59 pounds. Slightly anemic and very nervous. The boy was taken to a pediatrician who made

a diagnosis of tuberculosis on a positive intracutaneous tuberculin test. Ordered rest. On auscultation of abdomen the hypermotility was extreme, loud and continuous. Luminal grains one-quarter, t. i. d. were given, rest advised. Weight increased from 59 to 64 pounds. Nervousness and twitching of face disappeared. Hypermotility considerably diminished. Child is improved,

Case 2—Man 35 years. Has been troubled with gas for the past two years. For the last year the trouble has been aggravated. Has been under considerable nervous strain. About three months ago was advised to go to a medical clinic where his gastro-intestinal tract was X-rayed completely, besides a complete phyical examination. Nothing pathological was found. He was told to take soda and warned not to let his bowels become constipated. On auscultation of abdomen, marked hypermotility was noted. This was almost continuous. He was treated with luminal and belladonna. Inside of a week he reported that the discomfort had practically ceased.

Case 3—Business man, 32 years old, has been complaining of discomfort and pain in upper abdomen for past year. He is troubled a good deal with gas. Tongue is coated most of the time. Bowels move twice a day. Pain is worse for an hour to an hour and a half after eating. A diagnosis of ulcer was made, but repeated X-ray examinations have failed to show any ulcer. The only positive finding was hypermotility. He has been treated with alkalies and diet for the past year with no improvement. Auscultation revealed a marked hypermotility with no quiet intervals. After four days, treatment with luminal and belladonna, reported that his symptoms had almost disappeared.

INCIDENCE OF FRACTURE OF THE SKULL WITHOUT DEFINITE CLINICAL SIGNS

By SAMUEL I. MULLER, M.D., LONG ISLAND CITY, N. Y.

THE classical symptoms of fracture of the skull commonly noted in major accidents and in the texts, are seldom seen in the course of even an active general practice. The fractures of the skull, to which we refer in this article, have as their only point of similarity, with the aforegoing, their production by an external force.

The etiology of these fractures was trauma occurring in daily activities of life, such as while walking, slipping on icy sidewalks, being pushed, falling from short heights and as applied to children during the course of play.

The symptoms were very mild. *Vomiting* sometimes occurs, consisting usually of one occurrence and not forcible, *Headache* of mild character, lasting from a few minutes to a few hours was present in some. *Pain,* if present, was limited to the site of the injury and then sometimes only on pressure, if a contusion or slight abrasion were present. *Swelling* was generally absent or very slight if present. In only one instance of this recorded series was *bleeding* and *laceration* present. This was the only instance of diagnosis of fracture of the skull, without any symptoms of any kind, made without *x*-ray examination. The fracture was visible through the laceration. Aside from the evident injury there was no complaint of any kind that would lead one to suspect fracture.

It is to be particularly noted that there was no unconsciousness, no nasal or aural bleeding and no changes in the pupillary reactions or size.

The diagnosis was made by *x*-ray examination. To cite more definitely, several clear cut examples have been selected.

Boy H., five years of age, was pushed by his older brother down a flight of stairs. He was found at the doorway of the house, crying from fright. A small swelling was noted over the occiput, on the right side. There was no other symptom present. *X*-ray examination made to satisfy the parent disclosed a small fracture of the occipital bone, running from the basilar suture to the masto-occipital suture on the right side and still another smaller similar fracture on the left side, on which side, there were no symptoms at all to be observed. The boy refused to remain in bed after the first day and went on to a complete recovery.

Boy C, aged ten years, fell from a fence, about four and one-half feet high, while playing, hitting the back of his head. He complained of mild headache. There were no other symptoms, other than pain on digital pressure to the area of contact of skull and ground. *X*-ray examination disclosed a comminuted fracture of the occipital bone, with lines of fracture radiating toward the lambdoidal suture.

Girl W, age twelve years, was pushed over a

small cement coping, a foot high and struck the back of her head She vomited once and disclosed on examination a very slight abrasion with almost no swelling There were no other symptoms An x-ray examination disclosed a fracture of the occipital bone, running upward toward the lambdoidal suture

Mrs B, age 35 years, was hit on the top of the head by a sash window ventilator falling from the roof of a trolley car, a distance of something more than two feet She complained of hysteria and pain on digital pressure to the site of injury Two weeks after the accident an x ray examination disclosed a fracture of the left parietal bone, almost parallel with the coronal suture and joining it at its junction with the sagittal suture, the bregma

Mr B, age 41 years, while walking, slipped striking the back of his head He complained of headache lasting one day and feeling of pressure on his head X ray examination disclosed a fracture of the left parietal bone, running almost parallel with the sagittal suture and joining the lambdoidal suture posteriorly

Boy G, age eleven years, while playing in a lot fell on a stone and received a laceration of the scalp, left parietal region, two inches long, with much bleeding He was brought in by his sister, walking While cleansing and shaving the area preparatory to sterilization and suture, the wound edges were separated, debris removed from the wound, the skull table distinctly seen with a very evident linear fracture of the left parietal bone, running parallel with the sagittal suture There was absolutely no other symptom of fracture of the skull other than the actual visualization of the fracture through the open wound The mother refused to hospitalize the boy and he went on to an uneventful recovery

Thus far all the enumerated cases have had no neurological symptoms of any kind, since their respective accidents

In the examples enumerated the usual habits of life were not interrupted because of the symptoms, if any, complained of Only on the findings of the x-ray examination were quiet, rest, the application of an occasional ice bag to the head ordered for a few days, more as a precautionary measure than a necessity

We can conclude that in the presence of fracture of the skull, per se, without injury to the underlying brain or its coverings, without compression from swelling or displacement of the bone, there are few symptoms if any, to lead one to suspect the presence of such fracture This can be more readily understood from a study of the structure of the skull itself and the fact that through it, is explained the absence of displacement in the presence of fracture of the cranial bones, which initiated from a force of minor character The importance of knowing the presence of such fractures is a matter more of prevention, the possible avoidance of complications of infection and an explanation of some of the otherwise obscure neurological symptoms, hardly possible without this known pathology Otherwise unexplained syncope or convulsions would be understood and a means of cure pointed out by the relief of local pathology

It is of further interest to note that most of the above findings were missed with the application of the usual technique of skull examination The x ray exposures were then made with the subject lying face upward the tube tilted at a 20° angle at a distance from the subject of 25 inches (exception Mrs B, P 9), with the tube centered so that a line from it passes almost through the foramen magnum of the occipital bone The end result is a film which shows the entire occipital bone with its foramen magnum the various portions of the temporal bone, the posterior portions of the parietal bones, with all their sutures There is nothing original about this technique It is mentioned because of its superiority in obtaining findings, in this portion of the skull, frequently missed by other exposures In some phases of practice these cases present a medicolegal interest of definite importance

VACATION TIME

Medical editors and advertisers take no vacations, and an increasing number of physicians make serious plans to catch up with their professional literature by reading their Journals during their vacations. Whether or not the readers accomplish all that they plan, their intentions encourage the editors to maintain the winter standards of the NEW YORK STATE JOURNAL OF MEDICINE during the summer months. Only in one respect will the editors feel a handicap,—few county societies or committees hold meetings, and so the pages of the News department may be limited. But all the other departments will be as full and as interesting as ever.

THE NEW YORK STATE SANITARY OFFICERS ASSOCIATION

The twenty-first annual meeting of the State Sanitary Officers Association, held in Saratoga Springs on June 30th, recalls the essential service rendered to public health by the organization The Association is an outgrowth of the annual official conference of health officers conducted by the State Department of Health beginning in 1901 in accordance with Section 21 of the Public Health Law The Association itself was organized in 1910 at the time of the annual conference for the purpose of enabling the health officers of the towns, villages and small cities to discuss their common problems with freedom, but before they had formed an organization they had taken a deep interest in the newer developments of sanitation and public health

Over one half of the doctors in the rural sections of New York are health officers and have always taken an active interest in public health discussions in the medical societies of the counties and state In fact, they were the first body to suggest the practice of those forms of public health which are now considered commonplace While the health officers in those early days were ambitious to do good public health work, they were powerless in their position between indifferent boards of health on the one hand and an unequipped State Department of Health on the other, yet under these adverse conditions the health officers themselves took action to improve the practice of public health in their communities

The germ of the organization of health officers was the custom of the secretaries of the county societies to hold an informal dinner at some time during each annual meeting of the State Society The leaders in these conferences were health officers who were also secretaries of their county societies, and thte principal topic discussed was the relation of family physicians to the practice of public health The conferences were modest affairs, but the ideas of leadership there expressed later developed into the fundamental policies of two major committees of the Medical Society of the State of New York—that on Public Relations, and that on Public Health and Medical Education—while the custom of the annual conferences of county secretaries has been continued by the State Society

The Health Officers Association entered the field of legislation during the year following its organization, when it introduced a bill in the legislature protecting the health officers against malpractice suits The Association had no support at all from other organizations, and yet the legislature passed this bill, but the Governor vetoed it for no discoverable reason The success of the health officers was a demonstration of the willingness of the legislators to give serious heed to public health measures

When the revision of the Public Health Law was under way in 1912 and 1913, it was the definite stand taken by the Health Officers Association that secured the passage of the bill The Commission appointed by Governor Sultzer to suggest revisions of the public health law had not given sufficient publicity to their deliberations, and as a result the legislative committee of the State Medical Society opposed the bill without having studied its contents However the officers of the Health Officers Association had attended the hearings of the commission and had been consulted in an essential way while the bill was in the process of drafting The final demonstration of their influence occurred in the hearing before the Legislative Committee when the health officers showed that both they and their colleagues in the County Medical Societies were whole hearted in their support of the bill

This story of the support of modern public health measures and methods by the rural health officers forms a background illustrating the present policy of the health officers The Health Officers Association in its meeting on June 30, 1931, reaffirmed its support of the plan for county health departments, but it also adhered to the plan to retain the present system of a board of health and a health officer in every town, village and city, which should have concurrent jurisdiction with the county departments The Health Officers felt the need of developing local initiative and responsibility in public health matters especially in sanitation and the ordinary control of communicable diseases The health officers believed that this local leadership could come only when provision is made for its exercise

CANCER PREVENTION

The prevention of cancer is a problem which belongs to the medical profession almost exclusively Tuberculosis is greatly affected by one's mode of living and methods of work, and its incidence and progress are lessened by the higher standards of living which go with education and culture and an improved financial status Cancer on the other hand, is progressive and a spontaneous cure is not to be expected, but when it once gets a start, it will continue to spread until it destroys life, unless it receives skillful treatment by a physician

The reduction in the menace of tuberculosis, following campaigns to educate the people, has led to reasonable expectations that similar results will follow the education of the people regarding cancer. The essential point to be emphasized in tuberculosis prevention is that of early diagnosis and treatment. This same principle holds good for cancer.

Today, the word cancer inspires the same fear that the word tuberculosis, or consumption, aroused a half century ago. Physicians can now talk with an assurance that was absent in the previous generation when tuberculosis was known in only its fully developed stage. Actual experience has shown that when a lecture on cancer is announced to a woman's club, the majority of members will stay away. They expect to hear nothing but doleful helplessness and fateful doom.

There is no need that a lecturer frighten the people, for they are in a panicky fear already. It may even be true that a description of the signs of incipient cancer does harm, either by arousing a fear that will keep the patient away from the doctor, or by lulling the patient into a false security when the signs of cancer are not absolutely positive.

A physician giving a popular lecture on cancer is on safe ground if he confines himself to the preclinical signs of cancer. He can explain that most cancers begin as persistent scabs, sores, lumps, or discharges which are not cancers, but are readily curable. It may not even be wise to tell the people that these are potential cancers, for malignancy develops in them only about once in five hundred cases. However, if everybody could get rid of these troublesome conditions, few cancers would develop. Hopeful lectures along this line make a good start in the campaign against cancer. (See page 922.)

DR. JOHN OSBORN POLAK

Dr. John Osborn Polak of Brooklyn, who died suddenly and unexpectedly on June twenty-ninth, aged sixty-one, belonged to the entire medical profession. A born teacher, and a recognized authority in gynecology, he delighted to accept invitations from medical societies to address the members with friendly intimacy. He had the happy faculty of clothing scientific principles with attractive simplicity, and transparent clearness. He was a central figure in the post-graduate courses of the Medical Society of the State of New York.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Effects of Light on Infections: An example of hope deferred and unrealized expectations is afforded by the following abstracts from an editorial in this Journal of July, 1906, on the effects of light on infections:

"Weak solutions of eosin in the presence of sunlight have been found to have a decided effect upon certain micro-organisms and ferments, which are not elicited in the dark. Diastase and trypsin are especially susceptible. The toxins of diphtheria, tetanus and snake venom are destroyed or rendered less toxic by this action. A solution of a fluorescent substance injected into the superficial tissues of an animal, and exposed to the sunlight, causes a destruction of the tissues and sloughing, which would not occur in the dark with the injection alone or in the sunlight without the injection.

"Mice were injected with a virulent culture of trypanosoma and then with a weak eosin or erythrosin solution, and exposed to sunlight for seven hours daily. Three days later no trypanosoma were to be found in the blood. The control animals, kept in the dark, died with blood swarming with parasites. The sun-exposed animals recovered. When infected animals were not injected with the fluorescent body until the day following the infection they died in four days, despite the sun exposure.

"This work is still in an experimental state, but it promises interesting revelations. Just how far its therapeutic value may reach, is difficult to determine; but we can see in it a powerful therapeutic agency."

The editorial fortunately ended with the following warning:

"It is to be hoped that conclusions will not be arrived at until experiment and study have thrown more light upon the subject."

MEDICAL PROGRESS

New Methods of Scarlet Fever Serum Therapy.—Friedemann, Schmerel, and Lukas state that while there is widespread agreement in regard to the prompt effectiveness of scarlet fever serum the largeness of the dose necessary to produce defervescence has hitherto stood in the way of its general introduction into practice, from 15 to 50 c c or more being required, according to the gravity of the case Intramuscular injection of such amounts is impracticable not only because of the high cost but also because the ordinary practising physician has not sufficiently large syringes for such dosage In addition the probability of serum sickness following must be taken into account The good results reported by certain Russian workers from intralumbar serum therapy induced the authors to try that method They were able in 5 cases to overcome all the acute symptoms of intoxication by one tenth of the amount of serum that would have been necessary for intramuscular administration Since, however, the technique of the intralumbar method of injection is too complicated to be suited to general practice the authors conceived the idea that intravenous injection might give the same good results They soon proved in 26 cases (16 adults and 10 children) that the same low dosage worked more quickly intravenously than intramuscularly, and that the exanthem usually disappeared after 6 hours instead of 24 48 hours In addition, the temperature dropped to normal in 6 7 hours in most cases The best practical value lay in the lessening of the number of cases of serum sickness, only 2 such occurring, and these very light in contrast with 8 or 9 severe cases observed after intramuscular administration Moderately severe cases of scarlet fever require 2 to 3 c c of serum in children and 3 c c in adults, severe cases 3 to 5 c c in children and 5 c c in adults It must be assumed that in intramuscular administration most of the serum does not enter the circulation but remains bound at the site of injection—a disadvantage not met in intravenous injection Care must be taken that the serum is free from carbolic acid and tricresol, which many firms add as disinfectants Since some persons have a congenital idiosyncrasy for any horse serum, a test should be made in advance with an intracutaneous injection of 1 c c Hypersensitive persons react within 10 minutes with an urticarial reddening In such subjects and also in all who have previously suffered with serum sickness, intravenous administration is contraindicated — *Deutsche medizinische Wochenschrift*, May 1, 1931

Health Advice Indicated in the Earlier Manifestations of Cardiovascular Disease — Kenneth A MacKenzie considers more particularly the management of cardiac disorders revealed by the periodic health examination, and in which symptoms are either absent or such as to cause little or no concern He emphasizes the facts that many of the distressing features in these disorders are psychic in origin and must be treated by mental measures, and that pessimism in regard to cardiac therapy is not justified The tolerance of the patient is the best guide to the degree and amount of rest and exercise most suitable Moderate exercise is usually well tolerated, strenuous exercise should be forbidden The patient has a right to get a definite opinion as to what he can do with safety, whether he can play tennis or golf, and whether he can walk one mile or five There is no special diet for organic heart disease, In arteriosclerosis a diet low in proteins and total calories is most satisfactory, provided it is not reduced too low Focal infections should be eradicated when possible, especially those of the teeth and tonsils, but deeply seated infections, as of the gallbladder, appendix, prostrate, tubes, etc, should be dealt with conservatively, as eradication is a serious matter The indications for symptomatic treatment are obvious For insomnia, simple hypnotics such as hot drinks, bromides, luminal, etc, are indicated For mild anginal pain nitroglycerin, bromides, chloral, etc, may be given Digitalis has no place in this class of patients Psychotherapy is a factor of major importance A painstaking history and physical examination will convince the patient that you are interested in his problem, and will establish confidence Positive assertions of normal findings, such as "Your lungs are normal, your pulse is strong and regular," act as helpful suggestions A half-hour talk with the patient is the most valuable part of the consultation The main object of this is to combat fear, which is harmful and should be avoided Frankly state your findings, admitting the patient's disability, but in a manner which will cause the minimum of fear Such statements as "People with a defect like yours live for many years and enjoy life," "Your defect is not serious, but worth looking after," are true and helpful One must attack the subconscious and the procedures suggested are effective weapons — *Canadian Medical Association Journal*, May, 1931, xxiv, 5

Treatment of Angina Agranulocytotica — According to Karl Neidhardt, angina agranulocytotica is known to be characterized by leucopenia and relative lymphocytosis The total number of leucocytes may fall to 100 per cubic millimeter In the smear, cells of the myeloid system are al

most wholly missing. The absolute lymphocyte count, however, is customarily below normal. Neidhardt presents an illustrative case in a woman of 42 whose symptoms began with the usual chill and rise of temperature accompanied by a characteristic bilateral follicular angina. Leucocytes, which were 2800 at the onset, fell to 500, 97 per cent of which were lymphocytes. Granulocytes, that is to say, cells of myeloid character, were almost entirely absent in the smear. The blood picture, together with the feverish angina, slight icterus, and normal platelet count, led to a diagnosis of angina agranulocytotica. In view of the patient's very grave condition and the unfavorable prognosis, it was decided to try the effect of the irradiation of the bone-marrow. The patient was accordingly given 5 per cent of an erythema dose under hard filtration on both the lower leg and the thigh. The leucocytes rose in 2 hours to 800; they were 1700 after 8 hours, and had reached 3800 on the second day. A second irradiation was given on this day, on the upper and lower arm, which brought the leucocyte count to 9200, 6 hours later. The number of granulocytes increased in the blood, simultaneously, being 16 per cent 24 hours after the first irradiation and 34 per cent on the following day. Meanwhile the percentage of lymphocytes declined until it was only 22 on the third day after the first irradiation. Later on a true leucocytosis of 20,000 was reached, with a great increase of granular forms, which is shown in a graph. The patient's recovery proceeded pari passu with the change in the blood picture. There could be no question but that this was a true angina agranulocytotica. Angina with lymphathic reaction and also an aleucemic form of leucemia could be excluded. The prognosis of angina agranulocytotica is known to be very poor, over 90 per cent of cases terminating fatally. The dramatic change in the condition of the patient in this case after stimulation of the bone-marrow by irradiation points to the desirability of employing roentgen rays in the future in all cases of agranulocytosis.—*Münchener medizinische Wochenschrift*, April 24, 1931.

Pyretotherapy: Advantages and Disadvantages of the Various Methods of Producing Therapeutic Fever at the Present Time.—J. Cash King lists and discusses the following methods of producing therapeutic fever: (1) Injection of foreign proteins and other toxic substances; (2) malarial inoculations; (3) diathermy; (4) high frequency electrostatic field; (5) hydrotherapy. The injection of foreign proteins and other toxins is very painful and many times there are disabling local results. Malarial inoculations have a mortality of from 1 to 5 per cent, give the patient a disease difficult to cure, and the intensity and severity of the attacks cannot be controlled. Furthermore, the desired strain of plasmodium is often not available, medicinal treatment cannot be given simultaneously, and certain individuals are immune to malaria. To avoid the disadvantages of these methods the author and his collaborators worked out the diathermic method, and in November, 1929, reported their results in 12 cases, in which eight to twelve treatments were given at intervals similar to the malarial paroxysm. At the present time two of these patients are carrying on their original occupations and five have maintained or shown further improvement. The results in these cases afford conclusive evidence that the benefits derived in the past from fever therapy have been entirely due to the accompanying elevation in temperature and not to any associated biochemical or pathological change. If a therapeutic measure is to occupy a permanent place in medicine, it must afford the simplest, quickest, and least expensive known method of bringing about the desired result. It is not certain that diathermy meets these specifications. The high frequency electrostatic field as a means of producing therapeutic fever can be dismissed until it is rendered simpler and less expensive. The general body temperature can easily be raised to any desired point by the use of certain forms of baths. Any full-sized bathtub serves the purpose. After the patient has been in the water for a few minutes, hot water is allowed to run in slowly, while the excess water is permitted to run out through the overflow drain. Thus the water is kept at the highest temperature the patient can stand—if possible, 110°F. A mouth temperature of 103.5° to 104.5° can usually be obtained in an hour or less. During the bath the temperature should be taken every ten minutes. By keeping the patient carefully wrapped and in a warm room the temperature can be maintained without difficulty. King concludes that pyretotherapy has an important place in therapeutics, but is not a panacea.—*Physical Therapeutics*, April, 1931, xlix, 4.

The Action of Radon in Chronic Rheumatism.—In the past, say Rathery and Monnery, in the *Bulletin de l'Académie de Médecine of* April 14, 1931, the radiotherapeutic action of radon (radium emanation) has not been susceptible of general application because of the lack of precision in dosage and methods and consequently uncertain results. Since 1929, these authors have taken up the question of its use from both a biological and clinical point of view. Radon, being a very diffusible and soluble gas, can be administered either through the lungs or by ingestion. The latter mode has been chosen as better adapted for precise dosage. The radon is obtained by means of a special apparatus invented by Lepape, which liberates a definite amount of radon from a known weight of a radium salt in aqueous solution. It is dissolved in a certain volume of water, and a known quantity of the

latter is given to the patient to drink. Thus the amount of radon introduced into the organism is known as exactly as is necessary. Treatments consisted of 150 to 300 millimicrocuries per day. They were administered to 25 rheumatic subjects with various articular symptoms, subacute or chronic, the cases being classifiable as those of gouty hyperuricemic, type, of simple chronic rheumatism, and of arthritis deformans. All were kept on a fixed diet, poor in purins. They were given daily, usually for a month, the required amount of radioactive water to drink, all at one time, with all other forms of medication excluded. Regular records were kept of 24-hour urine, showing variations of diuresis and of excretion of urea, total purins, and uric acid. At the same time precise dosage made it possible to evaluate the variations of these elements in the blood. In the great majority of cases, radon caused: (1) increased diuresis, usually reaching its maximum in the second week; (2) increased excretion of purins and uric acid, mostly running parallel; (3) no appreciable change in urea elimination; (4) a lowering of blood uric acid, sometimes by as much as 40 percent, always coinciding with increased excretion of the same. It appears that rheumatism causes a functional hyperactivity of the kidneys that is elective for elimination of uric acid. In all but two far advanced cases the findings were very favorable. Always there was a sedative action, usually very prompt; in some cases this was the only perceptible result; but frequently there was a local action on the tissues, with diminution of swelling or restored motility of articulations. The general condition improved, the patients gained weight, and the differential blood count underwent favorable modification. Treatment should begin with the weak doses and increase gradually. The amount of radon used was somewhat greater than that in thermal waters, but still not very far from these.

Physiological Principles in the Treatment of Asthma.—R. J. S. McDowall, writing in the *Practitioner*, May, 1931, cxxvi, 5, points out that in the treatment of asthma the indication is for procedures which stimulate the sympathetic nerves and dilate the bronchi. For this, subcutaneous injection of adrenaline (0.5 mg.) has become almost routine. The sympathetic may also be stimulated by cold sponging with rough towelling or by asphyxia. In emergency temporary asphyxia may be produced by having the patient put his head under the bed clothes; this may abort an attack. Atropine, which acts by paralyzing the nerve endings of the vagus, is of special value in cases of nervous origin, but it is of no avail when the stimulus to the vagus is chemical. Inhalants, such as stramonium leaves, are harmful in the long run, as they leave the bronchi more sensitive than before. In the prevention of an attack regular exercise and stimulation of the skin, produced electrically or mechanically, is most important. A cold bath should be recommended, as in that way the suprarenals are stimulated. The evidence that asthma may be related to the entrance from the bowel of foreign proteins, which may sensitize the body to nervous and chemical mechanisms, calls attention to the necessity for careful attention to the diet, especially anything that interferes with protein digestion. Hence fats and excessive consumption of carbohydrates should be avoided. Meat and meat extracts, which stimulate the gastric secretion, are advantageous. Nasal treatment, which has been extensively advocated, seldom effects a permanent cure. Every effort should be made to discover hypersensitivity to any class of substances or circumstances which aggravate or alleviate the condition. If the gastric secretion is defective, hydrochloric acid and pepsin are indicated, and have been found valuable in children. The fact that experimentally increased hydrogen ion concentration dilates the bronchi suggests that substances tending to produce an acidosis, such as ammonium chloride and aspirin, may be valuable. Where the pulse is slow and the skin dry thyroid extract may be expected to stimulate the sympathetic. Attacks may be controlled almost indefinitely by ephedrine (5 to 15 centigrams), but adrenalin is ineffective after ephedrine. Two drug treatments have not been adequately tried. Since a reduction in blood potassium has been described in asthma, potassium therapy appears to be indicated and deserves a thorough trial. There is good experimental evidence in favor of minute injections of pilocarpine. In cases in which the symptoms are due to sympathetic exhaustion, which cannot be relieved by stimulating, a secretion of adrenalin, absolute rest, nervous depressants, or even hypnotics, are indicated.

On a Common Type of Chronic Colitis which is Seldom Recognized.—Aldo Castellani recalls that in 1905 and 1906, while in Ceylon, he observed cases of pyrexial colitis, at times with severe diarrhea, but without pus and blood in the stools. As etiological agents he found and described two organisms, which he called *B. ceylonensis* A, and *B. ceylonensis* B. This type of colitis is not confined to the tropics, but is common in the subtropics and the temperate zones. During the past four years, he has observed 81 cases of this condition, which is characterized by recurrent attacks of diarrhea, usually non-dysenteric; vague abdominal symptoms between the attacks; general fatigue and nervousness. The disease may persist for years. A positive diagnosis can be made only by bacteriological methods. The blood of every suspicious case should be tested for *B. ceylonensis* B, *B. ceylonensis* A, and *B. metadysentericus*. When the agglutination is higher than 1 in 80, repeated examinations of the stools will often reveal, sooner or later, the presence of

metadysentery organisms, though many examinations may have to be carried out before a successful one is obtained. The prognosis is bad, unless a correct diagnosis is established. The treatment is best carried out in a hospital or nursing home. It should begin with a dose of castor oil. Intestinal disinfectants, such as salol and kerol capsules, are useful in some cases. Preparations of acidophylus bacilli are occasionally helpful. Autogenous metadysenteric vaccines are of great value, though good results may also be obtained with stock metadysentery vaccine containing *B. ceylonensis* B, *B. ceylonensis* A, and *B. metadysentericus.* It should be given in small doses two or three times a week, for at least six weeks. The course should be repeated after an interval of from two to four months. In temperate climates milk is the best diet; in the tropics the diet should consist of albumen water, rice water, toast water, chicken broth, panpeptone, and peptonoids.—*Practitioner,* May, 1931, cxxvi, 5.

The Problem of Arterial Hypertension in Urinary Retention.—G. Wüllenweber, writing in the *Klinische Wochenschrift* of April 18, 1931, says that the origin of hypertension in prostatic hypertrophy is often given too mechanical an explanation and the hypertension considered a result of pressure injury to the kidney, where the pelves have been subjected to pressure, whereas the reversibility of the blood pressure in the disturbance of kidney function that is actually present and demonstrable shows that we must be dealing at the outset with purely functional matters. Moreover, the dependence of the pressure in the kidney pelves upon the bladder pressure has recently been demonstrated manometrically. To understand renal injury with high blood pressure, it is not necessary to conceive a stasis or an actual back *flow* from bladder to ureter, pelvis, and calyx—however common this procedure may be. The pressure relations in bladder, ureter, pelvis, and kidney with their effect on arterial blood pressure are closely connected in a reflex way, and may react as a unitary system. The most frequent cause of urine retention, clinically speaking, is prostatic hypertrophy. There seems to be little in the literature concerning the stage of such hypertrophy at which increased blood pressure first makes its appearance. On the basis of three illustrative cases, Wüllenweber shows that in urinary retention hypertension with all its sequels can be found without the patient having suspected that he was ill. In one case, retention had led even to maximal trabeculated bladder, dilatation of ureters, contracted kidney, and arterial hypertension without the patient having experienced the slightest subjective symptoms on the part of the urinary organs. Here the bladder in its efforts to help itself had formed trabeculae that increased the intravesical pressure, all unknown to the patient; this had led to compensatory measures on the part of the general organism, expressed in the arterial system as hypertension and cardiac hypertrophy. Hypertension may exist before residual urine is present. These cases teach the importance of examining the prostate in every case of hypertension. It seems very pertinent to ask whether the indication for operation in the prostatic patient should be determined —as is now generally done—practically exclusively according to the degree of urinary retention in the bladder, or whether we should instead inquire (which is far more important) whether the entire arterial system is not threatened with danger, even though there is no residual urine, and no appreciable difficulty in urinating.

The Hydrogen Ion Concentration in the Blood of the Aged.—Giulio Maragliano, writing in the *Riforma medica* of April 27, 1931, says there is a tendency today to recognize a life cycle in every individual, which begins with the vagotonia of infancy, expressed in alkalosis, and ends with the sympathicotonia of old age, expressed in acidosis. With a view to testing the correctness of this current impression, that the blood of aged persons exhibits an acid orientation, he made a study of the hydrogen ion concentration in a group of subjects whose ages, with one exception, ranged between 54 and 90, one man of 45 being included in the study because of premature senility. Using an electrode of the Verain type with a small bubble of hydrogen, he first obtained in a series of youths values approximating the classic value of 7.35 at a temperature of 18° C. (64.4° F.), which is accepted by all authors as a mean normal value. He took the blood to be examined from the ulnar vein alone, and did not subject the patients to the annoyance of the withdrawal of arterial blood in addition, in view of the slightness of the difference in pH (0.01 to 0.04 according to other authors) between the two bloods, and the danger of producing a painful hematoma. He was careful to choose only patients who were not suffering with any diseases in which the value of the pH tends to be displaced. All the individuals were affected with arteriosclerosis in greater or less degree; one suffered with senile dementia, one was blind, one an idiot, one exhibited dorsal kyphosis and one an advanced stage of senile involution. The blood was withdrawn in the morning on a fasting stomach, before the patients had been subjected to any muscular fatigue. In every case the values obtained were on the side of acidity and never on that of alkalinity. In 4 cases the pH was 7.30, and hence within physiologic limits; in 6 it ranged between 7.29 and 7.27; in 5 it was between 7.25 and 7.20; in a single case (the kyphotic patient, a man of 88 in a state of mental childhood) it had an average value as low as 7.15 after many tests had been compared. Although the number of cases studied was not large, it is certainly justifiable to conclude that in the blood of the aged a clear orientation toward acidity can be established.

LEGAL

OPERATION WITHOUT CONSENT

By Lorenz J Brosnan, Esq
Counsel Medical Society of the State of New York

Every human being of adult years and sound mind has the right to determine what shall be done with his own body, and a surgeon who performs an operation without his patient's consent commits an assault, for which he is liable in damages, except in cases of emergency where the patient is unconscious, and where it is necessary to operate before consent can be obtained"

This language is taken from an opinion of one of the most distinguished jurists in the United States, Chief Judge Cardozo of the Court of Appeals of this State It is incumbent, therefore, upon a physician to obtain the consent of the patient before operation For his own protection, this consent should be secured in writing and witnessed by some disinterested party The written consent obtained should give the surgeon discretion to perform any operation which in his opinion he deems necessary within the surgical field From the standpoint of prudence and to protect himself against subsequent claims the surgeon should in the case of a married woman not only obtain her consent but also the consent of the husband

A physician should be especially careful not to operate upon a minor or an insane or incompetent person without the consent of the parents or guardian of the minor or the committee of the incompetent In the Medico-Legal Principles, which appear as Appendix II to the Principles of Professional Conduct of the Medical Society of the State of New York, the rule is stated in Sec 14 as follows

"Where a person to be operated upon is a minor or incompetent, the consent of someone legally authorized to give such consent should be obtained Parents or guardians of minors are persons legally authorized in cases of minors and a committee or guardian in case of an incompetent"

The rule that consent to operate must be obtained in the first instance does not, of course, obtain in cases of emergency where the patient is unconscious and where it is necessary to operate before consent can be obtained

We stress in this editorial the necessity for written consent since experience shows that there is a certain class of patients who will repudiate an oral consent, leaving the surgeon in the position where he is compelled to put his word against the word of the patient and perhaps several members of the family It should be remembered that the question as to whether the operation was skillfully performed or whether it benefited the patient does not in any wise affect the patient's right to sue the physician if prior consent to the operation has not been obtained from the patient It is interesting to examine some of the cases where patients have sued physicians on the cause of action of operation without consent, and to note the rulings which the courts have made in these cases

In Minnesota an action was commenced against a physician and surgeon for claimed operation without consent upon the following state of facts The defendant, a physician and surgeon of high standing, was consulted by the plaintiff who complained of trouble with her right ear An examination disclosed a large perforation in the lower portion of the drum membrane and a large polyp in the middle ear, which indicated to the doctor that some of the small bones of the middle ear were probably diseased The defendant at this time also examined the left ear, but because of foreign substances in it was unable to make a full and complete diagnosis The defendant suggested operation and the plaintiff consented, understanding that it was only her right ear which required treatment At the hospital the defendant made a more complete and extended examination of the left ear which showed that this ear was in a more serious condition than the right ear upon which the defendant intended to operate This examination revealed a small perforation high up in the drum membrane, hooded and with granulated edges, and the bone of the inner wall of the middle ear was diseased and dead The defendant thereupon called this condition to the attention of the plaintiff's family physician who was present and who confirmed the diagnosis of the defendant The defendant thereupon performed an operation on the plaintiff's left ear, removing a portion of the drum membrane and scraping away the diseased portion of the inner wall of the ear This operation was in every way successfully and skillfully performed

The plaintiff however, claiming an assault and battery upon her person, sued the defendant and the jury returned a verdict in her favor for some $14,000 The defendant moved to set aside the verdict on two grounds, first, that it was against the weight of evidence, contrary to the evidence and contrary to the law and, secondly, that it was excessive The court denied the motion so far as it related to the weight of the evidence, but granted

the motion on the ground that the verdict was excessive. From this decision both plaintiff and defendant appealed. The decision was upheld in the higher court on the ground that the verdict was excessive, but the court pointed out that the defendant physician should not have operated on the left ear without the plaintiff's consent, holding that a physician and surgeon however skillful or eminent could not violate the bodily integrity of a patient by a major operation, placing him under an anesthesia and operating upon him without his consent or knowledge. The court also pointed out that this was not an emergency operation and that the defendant was not in a position to invoke the rule that where a person was injured to the extent that he was rendered unconscious and his injuries required prompt surgical attention, the physician called in to treat could do so without obtaining prior consent. It was urged by the defendant's attorney upon the court that the act of the defendant was not a battery in that it was not predicated on an evil intent but rather on a desire to effect a cure of this plaintiff's condition; but the court held that the operation being performed without consent made it wrongful, and if wrongful it was unlawful.

In a case in one of our Southern States, an infant eleven years of age accompanied by his adult sister was operated on by the defendant for adenoids. The evidence tended to show that the operation was performed at the request and in the presence of the child's sister. During the administration of the anesthetic the child died. An action was instituted against the defendant doctor by the parents of the deceased child, the complaint among other things alleging that "no person whomsoever had any authority to permit defendant to perform any operation upon their child and plaintiff and his wife had no knowledge that any operation was contemplated by anyone, especially by defendant at this time."

At the trial the defendant was not able to show that the plaintiffs had any knowledge of the fact of the contemplated operation nor was there any proof that the operation was an emergency one. Upon this state of facts the court instructed the jury, "If you believe from the evidence that the daughter of the plaintiffs took the child to the defendant for the purpose of being operated upon and you believe that the defendant in good faith performed the operation with ordinary care, your verdict must be for the defendant and this, too, notwithstanding there was no consent from the parents that the operation should be performed." The jury returned a verdict in favor of the defendant and the plaintiff appealed. In the higher court it was held that the charge of the lower court above quoted was erroneous since it placed the liability of the defendant on the same basis as if the parents had consented, and made the consent of the daughter as effective as that of the parents although they had never lodged such authority in the daughter; and it was further held that the only way that the daughter could consent to the operation and bind the parents to such consent would be if such authority had been delegated to her and she had acted as an agent under the circumstances.

An instance of the rule releasing the physician from the necessity of obtaining a consent where an emergency exists, is found in a case in Michigan where the plaintiff, a boy fifteen years of age, while crossing railroad tracks was hit by an engine and thrown under the wheels of the car. His left foot was mangled and crushed. Shortly after the accident the plaintiff was taken to a hospital and, after communicating his name and address to the attending surgeons, lapsed into complete unconsciousness. An examination and consultation by four surgeons was made and they decided that prompt surgical treatment was necessary. Thereupon the defendant surgeon was called and he concluded from his examination that an immediate amputation was necessary to save the boy's life. There were no relatives of the infant present, and the defendant knowing the distance from the hospital to the infant's home decided that there was not time enough to get there, procure consent and return to operate. The defendant finally amputated the foot and the boy's life was saved.

Thereafter an action was instituted by the parents, claiming that the defendant should not have amputated without their consent. The jury returned a verdict in favor of the defendant physician, and on appeal the judgment below was affirmed, the higher court saying in part: "Taking into consideration the condition in which the plaintiff was when the defendant reached him, we have no hesitation in holding that the defendant was amply justified in treating this case as an emergency and his conduct should be viewed in the light of legal principles governing such cases." The court also said that the work of a physician is highly humane and largely charitable in character, and no rule should be announced which would in any way tend to deprive those suffering from their services.

In another case in one of our Western States the plaintiff, a youth seventeen years of age, had a tumor on his left ear about the size of an egg. He consulted the defendant physician, a specialist, who advised operation. Three days later the plaintiff, accompanied by his aunt and sister, returned to the hospital to submit to the operation. In the course of the administration of the anesthesia, the boy died. Subsequently an action was begun by his father, claiming that he had not authorized the operation. There was a verdict in favor of the doctor which was affirmed in the higher court, the court stating that there was nothing in the record to indicate to the doctor that the father did not approve of the aunt and sister going with

the boy to the doctor to be operated upon and that under the circumstances disclosed the defendant should not be held liable because he did not obtain the consent of the father prior to the operation

In passing, it might be noted concerning this ruling that while the court in this case absolved the physician from the necessity of obtaining a written consent from the father, it is obvious that it did so since the record showed that the father had practically delegated the aunt and sister of the boy to act in his behalf so far as consent to operative interference was concerned

At this point it should be stated that where a minor comes to a doctor's office alone, and after examination the physician advises operation, such operation should not be performed until the physician has seen one or both of the parents and obtained their consent It is extremely unwise to rely upon the statements of minors that they have talked the matter over with their mother and father and that the latter have consented to the operation

In a case in New Jersey the plaintiff applied to the defendant, a physician, to operate on the plaintiff's left groin At the time fixed for operation the defendant and his assistants noticed that the plaintiff had a ruptured right groin which was in a more serious condition than the left He thereupon proceeded to operate upon the right groin, but by reason of the fact that the plaintiff came out of the anesthetic he was unable to continue the operation on the left groin This operation he intended to perform on the next day, but the plaintiff failed to appear and subsequently sued for alleged assault and battery

The plaintiff recovered a verdict of $1,000 in the trial court and the defendant appealed The Appellate Court reversed the judgment below, holding that before anesthesia had been perfected it was comparatively simple for the surgeon to solicit the consent of the patient during an operation, but now while the patient is unconscious it is of course impossible The court held that in the absence of a representative chosen by the patient, the surgeon selected by the patient becomes the patient's representative while the patient is under the anesthesia The court applied the maxim, "that one is presumed to accept that which is beneficial to him," and said that it was inconceivable that had the patient known the true condition of the right groin and the possibility of death by strangulation he would not have consented to the operation performed or relied on the judgment of the surgeon The court concluded that the operation was not in any sense against the will of the patient, nor was it an operation of a different sort than that which the patient had consented to undergo

Sufficient has been shown from these cases and the principles there enunciated to demonstrate the necessity of a surgeon obtaining consent prior to operation No surgeon can say with any degree of certainty what patient will claim that an operation was performed without his consent and, therefore, as a routine matter the written consent should be obtained in all cases

---

CLAIMED NEGLIGENT PLASTIC OPERATION ON NOSE

A young woman, twenty-four years of age, consulted the defendant who specialized in rhinoplastic surgery, with respect to the possibility of improving the appearance of her nose It was of the negroid type, flat based, saddle shaped, with an over-bulbous tip and unusually broad nostrils The doctor informed her that an operation might succeed in giving her a more shapely nose and she entered a hospital to have such operation performed

Under a local anesthetic of novocaine with adrenalin, the doctor reduced the bulbousness of the tip of the nose by intranasal incisions, removing a quantity of cartilage The doctor narrowed the broad bony base of the nose by intranasal incisions and sawing through the frontal processes of the right and left maxillae The width of the nostrils at the tip was reduced by nasal excisions and suturing The nose was packed with sterile gauze and immobilized with a cast and adhesive plaster The patient remained in the hospital for five days under the doctor's care

He also treated her after her return to her home, and when he last saw her about four weeks after the operation the nose was nearly healed and much improved in shape

The patient subsequently returned to the doctor's office complaining that the change in shape had not come up to her expectations, and asking that the doctor give her further operative treatment He advised against it and heard nothing more from the woman until a suit was started against him charging malpractice in that he had caused her nose to become permanently disfigured and marred, and claiming an impairment of the plaintiff's health An answer was interposed denying all allegations of negligence, but before the case could be reached for trial the defendant died A motion was made by your counsel and an order obtained from the court marking the action abated, thereby finally terminating the matter

NEWS NOTES

MEETING OF THE COUNCIL, JUNE 2nd, 1931

In accordance with Chapter IV of the By-Laws, the new Council convened in the Syracuse Hotel, Syracuse, June 2nd, 1931, at the close of the Annual Meeting of the House of Delegates with the following members present:

Drs. William D. Johnson, Charles G. Heyd, Daniel S. Dougherty, John A. Card, James F. Rooney, Arthur W. Booth, Nathan B. Van Etten, Harry R. Trick, Arthur J. Bedell, Thomas P. Farmer, Charles H. Goodrich, James E. Sadlier, Charles D. Kline, Herbert L. Odell, Frank vander Bogert, Augustus B. Santry, E. Carlton Foster and W. Ross Thomson.

The first order of business being the election of an Executive Committee to carry on during the interim between meetings of the Council, Drs. John A. Card, Arthur J. Bedell, Louis A. Van Kleeck, Augustus B. Santry and W. Ross Thomson were nominated by the President and were elected. Election of members of the Standing Committees was referred to the Executive Committee. It was decided that at the next Annual Meeting, one Session should be devoted to *x*-ray, and one Session to Physical Therapy.

Respectfully submitted,
D. S. DOUGHERTY, *Secretary.*

EXECUTIVE COMMITTEE MEETING, JUNE 2, 1931

Immediately following the adjournment of the Council the Executive Committee met and organized by electing Dr. William D. Johnson, Chairman, and Dr. John A. Card, Vice-Chairman. On motion duly made, seconded and carried, Dr. Orrin Sage Wightman was appointed Editor-in-Chief, Dr. Frank Overton, Executive Editor, Mr. Lorenz J. Brosnan, Legal Counsel, and Mr. Thomas A. Clearwater, Attorney. Dr. Charles H. Goodrich was made Chairman and Drs. Daniel S. Dougherty and Charles Gordon Heyd members of the Committee on Publication.

Drs. John A. Card, Daniel S. Dougherty and Frederic E. Sondern were appointed a Committee to prepare the Budget for the coming year and submit it to the Executive Committee for approval at the next meeting.

Respectfully submitted,
D. S. DOUGHERTY, *Secretary.*

EXECUTIVE COMMITTEE MEETING, JUNE 18, 1931

The regular meeting of the Executive Committee was held at the State Society rooms Thursday, June 18, 1931. Drs. William D. Johnson, John A. Card, Daniel S. Dougherty, Frederic E. Sondern, William H. Ross, Arthur J. Bedell, Louis A. Van Kleeck, Augustus B. Santry and W. Ross Thomson were present.

The following budget prepared by the Budget Committee was approved, and the Trustees were recommended to make the necessary appropriations:

BUDGET, JULY 1, 1931, TO JUNE 30, 1932

Rent	$2,900.00
Telephone	200.00
Postage	600.00
Stationery and Printing	900.00
Salaries	18,000.00
Contingent Fund	1,200.00
Annual Meeting—Printing and Postage, Stenographer for House of Delegates, and Exhibitors' Entertainment	2,000.00
District Branch Programs, printing and postage for mailing paid through Secretary's Office	700.00
Auditor	600.00
Traveling Expenses — General, President and Secretary	5,000.00
Traveling Expenses, A.M.A. Delegates	3,000.00
Counsel—Salary	14,000.00
Counsel—Expenses	300.00
Secretary—Honorarium	3,000.00
Secretary—Expenses	600.00
Executive Officer's Salary	9,000.00
Executive Officer's Expenses	1,500.00

STANDING COMMITTEES

Legislation	6,300.00
Medical Economics	2,000.00
Public Health and Medical Education	8,500.00
Public Relations	3,000.00
Medical Research	150.00
Scientific Work	500.00

SPECIAL COMMITTEES

Physical Therapy	800.00
Periodic Health Examination	1,000.00

DISTRICT BRANCHES

For Annual Meetings as allowed under the By-Laws	2,000.00

SPECIAL APPROPRIATIONS

Conference of County Secretaries	600.00
Conference, Executive Committees of District Branches	200.00
Christmas Bonus	600.00
Tri-State	100.00

JOURNAL

Printing and Cuts	35,000.00
Postage—Mailing Journal	3,600.00
Postage—General	400.00
Commissions	8,000.00
Traveling Expenses Advertising Manager	300.00
Honorarium—Editor-in-Chief	500.00
Executive Editor—Salary	5,000.00
Executive Editor—Traveling and Incidental Expenses for Reportorial Work	500.00
Dr. Stedman (Medical Progress Dept.)	1,200.00
Rent	1,658.00
Salaries	4,420.00
Extra Clerical Work for Executive Editor at Patchogue	500.00
Telephone	200.00
Subscriptions to Journals	250.00
Wrappers for Journals	600.00
Stationery and Printing—General Office Supplies, including Furniture, Fixtures, etc.	800.00

DIRECTORY

Printing Directory	14,000.00
Wrapping and Delivery	1,700.00
Postage	700.00
Commissions	700.00
Stationery, Printing and Expenses	700.00

(This budget was approved by the Trustees on June 26, 1931—Editorial note.)

The following members of standing committees were nominated by the President and duly elected. (The chairmen had already been elected by the House of Delegates, and are listed on page 767 of this Journal.

Legislation—Drs. John J. Buettner and Marshall Clinton.

Medical Economics—Drs. Frederic E. Elliott, Morris Rosenthal, Donald S. Childs, and Joseph P. Garen.

Public Health and Medical Education—Drs. George W. Kosmak, John O. Polak, Mahlon H. Atkinson, Leo F. Schiff, William A. Groat, Martin B. Tinker, Clayton W. Greene, and Edward G. Whipple.

Public Relations—Drs. Oliver W. H. Mitchell, Augustus J. Hambrook, George M. Fisher, and William H. Ross.

Medical Research—Drs. Augustus B. Wadsworth, Burton T. Simpson, Simon Flexner, Winfield W. Scott, Edwin MacDonald Stanton and Frederic E. Sondern.

Scientific Work—Dr. Henry S. Patterson.

The following special committees, appointed by the President, were confirmed by the Executive Committee:

Periodic Health Examinations—Dr. C. Ward Crampton, Chairman and Drs. Walter D. Ludlum, Walter A. Calihan, Nellis B. Foster, Guy H. Turrell, Harlow Brooks, Luther F. Warren Nelson G. Russell, Joseph D. Olin and Marion C Potter.

Physical Therapy—Dr. Richard Kovacs, Chairman, and Drs. Philip L. Forster, Guy H. Turrell, Frederic E. Elliott, Lee A. Hadley, George A. Leitner and Virginia C. Tannenbaum.

Prize Essays—Drs. Edwin MacD. Stanton, *Chairman*, Edgar A. Vander Veer and Stanhope Bayne-Jones.

To Revise the Constitution and By-Laws—Drs. Charles G. Heyd, John A. Card, Daniel S. Dougherty, Harry R. Trick, Thomas P. Farmer, James F. Rooney, and Walter D. Ludlum.

To Study the Ways and Means of Establishing a Retirement Fund for the Benefit of Members—Drs. William M. Patterson, Chairman, Nathan Ratnoff, Floyd S. Winslow, William H. Ross, and Dan Mellen.

To Study the Nurse Problem—Drs. Nathan B. Van Etten, *Chairman*, Andrew Sloan, J. Richard Kevin, George W. Kosmak, George R. Critchlow, Arthur S. Chittenden, George L. Brodhead, and Robert P. Munson.

Press Relations—Drs. Samuel J. Kopetzky, Edward C. Podvin, Alec N. Thomson, and Carl Boettiger. The appointment of the remainder of this Committee to be left until the fall.

To Draw Up Suitable Resolutions on the Death of Dr. E. Eliot Harris—Drs. John A. Card, Chairman, Daniel S. Dougherty and William H. Ross.

Woman's Auxiliary—Drs. John A. Card, Chairman, James N. Vander Veer and Homer J. Knickerbocker.

Insurance—Drs. John A. Card, Chairman, Charles G. Heyd and Frederic E. Sondern.

Dr. James N. Vander Veer was re-appointed as a representative from the State Society to act

with the State Department of Health in the campaign against Venereal Diseases.

The appointment of the Committee on Certification of Specialists was deferred until the fall.

The President, Secretary, Chairman of the Committee on Arrangements, and Chairman of the Committee on Scientific Work were appointed a Committee to decide the date of the next Annual Meeting, May 23rd being tentatively approved by the Executive Committee.

D. S. DOUGHERTY, *Secretary.*

PUBLIC RELATIONS COUNTY SURVEY, NUMBER 19—STEUBEN

MAY 27, 1931

Steuben County, New York, is situated in the center of the southern tier of counties bordering the northern boundary of the State of Pennsylvania. A total population of 82,671 was shown by the Census of 1930. The County contains 1401 square miles of territory and ranks sixth in size in the State of New York. It is essentially agricultural although there is considerable industrial activity to be found in the cities of Corning and Hornell.

There are eighty physicians practicing within the County at the present time distributed as follows: 18 in Corning, 22 in Hornell, 8 in Bath, while the remainder are well scattered in the smaller communities and rural sections. Of this number of physicians, there are 72 who are members of the Steuben County Medical Society.

The County is served by four general hospitals. Two in Hornell, namely: the St. James Mercy and the Bethesda; Bath Hospital in Bath; and Corning Hospital in Corning. All of these institutions are equipped with modern appliances. The Bath Hospital is more or less of a semi-private institution, being managed and operated by Doctors H. J. Wynkoop and Zeno Selleck. The Steuben County Tuberculosis Sanitarium is located at Bath. It is known as the Pleasant Valley Sanitarium and is operated under the direction of Dr. D. P. Mathewson. The capacity is 45 beds: 19 men; 14 women; and 12 children. The total number of persons receiving treatment during the year 1930 was 104, while the total operating and maintenance cost for the same period was $40,360.16.

The County of Steuben supports two public health nurses who divide the territory between them and work under the direction of the District Supervisor of the State Department of Public Health, Dr. John A. Conway and his assistant, Miss Hazel Stewart. The county nurses arrange for the holding of public clinics of various kinds including chest, mental, pre-natal, orthopedic, toxin-antitoxin, child consultation, dental, venereal, well-baby, etc. All clinics are conducted by specialists sent in for the most part by the State Department of Health, except as follows:

The dental, venereal and well-baby clinics are conducted by the health officers of the cities of Corning and Hornell, the county nurses being privileged to bring in county cases, whose residences are outside these cities, for examination or treatment. The chest clinics are conducted by Dr. D. P. Mathewson, Superintendent of the Steuben County Tuberculosis Hospital. In addition to the chest clinics that are held at regular intervals, the State Department of Health conducts an additional clinic with the aid of a portable *x*-ray, to which anyone in the County is admitted. We find that these State clinics are being patronized to a greater extent each year.

The County of Steuben maintains three laboratories with State aid, located at Corning, Bath and Hornell, affording to the County the following services, conducted under the direction of R. J. Shafer, M. D., and five assistants:

1. Examination of specimens submitted to determine presence of communicable diseases.
2. Regular bacteriological examinations of all milk produced and sold in the County.
3. Examination of all public water supplies at regular intervals.
4. Facilities used to assist physicians in the diagnosis of disease.
5. A total of 32,175 specimens examined during the year of 1930.

The laboratories also serve the New York State Department of Health as supply stations, furnishing physicians and health officers with antitoxine and sera. Immune sera for measles and poliomylitis are prepared by the Steuben County Laboratories for the New York State Department of Health.

The total cost of operation and maintenance of the laboratory system for the year 1930 was $10,875.00 which is paid in part by the New York State Department of Health.

The school districts of the cities of Corning and Hornell and village of Bath employ full-time school nurses. Other school districts in the County are taken care of by the County nurses.

In the spring of 1930 the Public Relations Committee of the Steuben County Medical Society sponsored the organization of the Steuben County Council on Public Relations made up of representatives of all organizations in the county interested in the maintenance of good health.

The purpose of this group was to disseminate accurate and reliable information on health subjects using whatever means might be available A Lay-Executive Committee was appointed consisting of the following Elmer E Meadley, Secretary of Corning Chamber of Commerce, Chairman, Mrs H C Bates, Corning, N Y, E R Hardenbrook, County Commissioner of Public Welfare, Dr E W Woodbury, Dentist and Miss Jessie M Ferguson, Supt of Davenport Home, Bath, N Y, Mrs Shirley E Brown, and Mrs Olive G Buisch of Hornell N Y who is General Manager of the *Evening Tribune Times*

This Committee prepared a definite program which was submitted to the members of the Steuben County Medical Society in October, 1930 The Society approved the program and the Committee has proceeded to carry out its plan This included the preparation of short articles by the members of the Steuben County Medical Society for syndication to the newspapers within the County who agreed to publish the articles regularly as released

It also involved the organization of a speakers' bureau among the members of the Medical Society for the purpose of giving addresses before various gatherings or organization meetings This work is now getting under way and has already shown promise of being very much worth while

Respectfully submitted,

PUBLIC RELATIONS COMMITTEE
H B SMITH, *Chairman*, Corning, N Y
GEORGE TAYLOR, Hornell, N Y
GUY PARKHURST, Bath, N Y

FOUR COUNTY MEETING

A joint meeting of the Medical Societies of the counties of St Lawrence, Franklin, Jefferson, and Lewis was held at the St Lawrence State Hospital, Ogdensburg, N Y, on June 25, 1931 A morning and an afternoon session were held, with a social luncheon at noon One hundred and twenty-five doctors were present, or sixty per cent of the membership of the four societies

The program was of great practical value to the members of the societies It was on the general subject of mental disease, and had been prepared by Dr P G Taddiken, Superintendent of the Hospital The official program was as follows

MORNING SESSION

Reception Building—10 15 *a m* (*Standard time*)

Address of Welcome — P G Taddiken M D, Superintendent

The Detection of the Future Neurosyphilitic Before Mental Symptoms Are Evident, — Harold H Berman, M D, Senior Assistant Physician

The Early Recognition of Mental Disease, — Leo P O'Donnell M D, Senior Assistant Physician

Mental Hygiene Clinics—Their Value and Uses, — Paul C Lybyer, M D, Director of Clinical Psychiatry

The Medical and Psychiatric Treatment at the St Lawrence State Hospital, — Harry J Worthington, M D, First Assistant Physician

The Results of Treatment — William L. Cudmore, M D, Senior Assistant Physician

CLINIC

Presentation of Typical Cases—Manic Depressive, Dementia Praecox (Schizophrenia), Psychoneuroses, General Paralysis etc etc.

Luncheon at 1 p m, Reception Building

AFTERNOON SESSION
2 15 p m

Demonstration of Spinal Anesthesia in Operations, — John E Free, M D, Consulting Surgeon, St Lawrence State Hospital (Operating Room—Main Building) 2 15 p m

Demonstration of Laboratory Methods, Lumbar Punctures and Tryparsamide Intravenous Treatment — Harold H Berman, M D, Senior Assistant Physician

Because of the length of the program there will be no general discussion After the morning session the writers of the papers will hold themselves available to answer any questions

Through the courtesy of the Ogdensburg Country Club, the privilege of the Golf Course is extended to those attending the meeting The Golf Club is situated eight miles from the City of Ogdensburg on the Ogdensburg-Morristown Road—Route 37

The papers of the sessions will be short and we hope, from the viewpoint of the general practitioner, practical

The Reception Building, Southwood, for tubercular patients, and the Nurses' Home, opened this year, are modern, fire proof, up-to-date structures, well adapted for the purposes intended All are invited to inspect these as well as the other buildings

Occupational therapy activities are carried on in the wards of the hospital and in various classes, and at Crafts, a pre industrial shop recently opened Arrangements will be made for those interested to visit this department

ANNUAL HEALTH OFFICERS' CONFERENCE

The annual conference of the Health Officers and Public Health Nurses of the State of New York was held in Saratoga Springs from Monday to Wednesday, June 29 to July 1, 1931.

This was the thirty-first conference, the first being held in 1901, the year of the establishment of the NEW YORK STATE JOURNAL OF MEDICINE. These conferences are official. The Public Health Law of the State, December 21, provides that the expenses of the Health Officers be paid by the municipalities which they represent. It is also the custom that the expenses of the Public Health Nurses be paid by the organizations that employ them.

The attendance at the conference was fully up to the usual standard, about 500 health officers and an equal number of public health nurses being present. Practically all those that attended were housed in the Grand Union Hotel, which followed its usual custom of opening one week in advance of the regular season in order to accommodate the delegates. The custom of housing everybody under one roof was most successful in promoting good fellowship and interest in the meetings.

The conference is to public health what the annual meeting of the Medical Society of the State of New York is to the private practice of medicine. The sessions were held both mornings and afternoons, with the evenings given largely to social functions. One of the most valuable and happy features of the conference was the acquaintances made and confidences exchanged while the participants sat on the spacious verandas.

The program included both scientific public health and also the practice of administrative medicine, or the duties of municipalities and voluntary organzations and the methods of their activities. The scientific program included discussions on the following:

Child hygiene and guidance.

The relation of constitution to disease.

The newer developments in milk inspection.

The common cold.

The parts of the program relating to administrative medicine were devoted largely to the duties of public health officers and voluntary organizations in their capacities as patients of those engaged in the scientific practice of public health.

The topics discussed included the following:

The Control of Syphilis in Rural Sections (see this Journal of June 1, 1931, page 720).

The Cooperation of the Public in Diphtheria Prevention.

The Public Health Program of the Mayor's Conference.

Methods of Cooperation in Health Services.

County Departments of Health.

The Relation of Public Health Nursing to the Practice of Medicine.

The State Sanitary Officers' Association held meetings on two afternoons and Tuesday evening. This organization was founded twenty-one years ago and has developed an increasing field of activity. The principal topic of the discussion was the County Department of Health and its relation to the local health boards in villages and townships. It seemed to be the consensus of opinion of the health officers that county departments of health were necessary in order to provide a staff of experts in public health, but also that the local boards of health and health officers should be preserved in their autonomy in order to develop a local initiative and responsibility. (See editorial, page 909).

The President of the Medical Society of the State of New York was recognized with a prominent place in the opening of the conference; and the intimate relation of the family doctor to public health work was emphasized throughout the conference.

CANCER COMMISSION IN CALIFORNIA

The following description of the formation of a Cancer Commission by the California Medical Association has been received from Dr. A. R. Kilgore, Secretary of the Commission. This action will be of interest to the physicians of New York State in view of the endorsement of cancer prevention by the House of Delegates (Journal, July 1, page 840).—*Editor's note.*

"At its annual meeting on April 27, the California Medical Association authorized the creation of a permanent Cancer Commission to represent the Association in all phases of the organized fight upon the increasing menace of this disease.

"As its first objective, the Commission plans to review and bring widely to the attention of the profession in California the most modern methods of diagnosis and treatment of cancer, and especially of early cancer, since it is obvious that increasing numbers of patients with early cancer are seeking advice.

"Later efforts will be directed toward education of the lay public on the signs and symptoms suggestive of early cancer. The establishment of specially equipped clinics and hospitals will be encouraged as well as more extensive clinical and laboratory research.

"It is a source of gratification to be able to inform you that the Commission has already been appointed, and that its plans of organization are well under way.

"The present members of the Commission, as appointed by the President of the California Medical Association are —

"Dr Charles A Dukes, Oakland, Chairman, Dr Lyell C. Kinney, San Diego, Vice chairman, Dr Alson R Kilgore, San Francisco, Secretary, Dr Harold Brunn, San Francisco, Dr Orville Meland, Los Angeles; Dr. William Ophuls, San Francisco, Dr C G Toland, Los Angeles; Dr H J Ullmann, Santa Barbara; Dr A H Zeiler, Los Angeles, Dr Junius B Harris, Sacramento, President of California Medical Association

ASSOCIATED PHYSICIANS OF LONG ISLAND

The ninety-ninth regular meeting of the Associated Physicians of Long Island was held on the afternoon of Saturday, June 20, at the South Shore Yacht Club, Freeport, Nassau County, with the President, Dr H C Courten, Richmond Hill, presiding Thirteen new members were elected, as follows

Frederick C Courten, M D, Richmond Hill,
Harry C Card, M D Jamaica;
Frank N Dealy, M D, Flushing,
Alexander S Walker, M D, Jamaica,
James H Watt, M D, Little Neck,
Stanley S Lamm, M D, Brooklyn,
Paul C Eschweiler, M D, Brooklyn;
Stanley D Banks, M D, Brooklyn;
Henry D Fearon, M D, Brooklyn,
I Theodore Rosen, M D, Brooklyn,
Theodore R Miner, M D, Brooklyn,
Bruce B Preas, M D, Rockville Center,
William C Brons, M D, Queens Village

The general program of the meeting was "Mosquito Elimination and Control in Nassau County," and was in charge of Dr A D Jaques, of Lynbrook, Treasurer of the Nassau County Mosquito Elimination Commission Dr. Jaques placed the working fleet of five boats at the disposal of the members, who enjoyed the afternoon on the Bay inspecting the work of ditching and draining the salt marshes and oiling the stagnant pools The Commission had almost completely accomplished the elimination of the salt marsh mosquito, the most troublesome variety, during the fifteen years of its existence, but the greatest obstacle now encountered is the "Improvements" now under way by which great areas of low marshland are filled with sand dredged from the bay, and thereby often enclosing stagnant pools, which require frequent oiling The newly-made land will become residential districts within a few years, but during the period of development it is a breeding ground for mosquitoes

The members enjoyed a social dinner in the early evening, after which Dr Jaques explained the work of mosquito elimination, illustrating it with moving pictures of the work in actual progress

JAMES COLT HANCOCK, *Secretary*

DISTRICT BRANCH MEETINGS

Conferences with the officers of the District Branches have been completed, and there follows a program of the annual meetings for this year

First	October 7	Newburgh
Second	November 19	Brooklyn
Third	September 16	Sharon Springs
Fourth	October 21-22	Glens Falls
Fifth	September 29	Rome
Sixth	September 22	Waverly
Seventh	September 24	Rochester
Eighth	October 1	Olean

The Fifth District could not definitely decide that the meeting should be held in Rome until the officers confer with Dr Bernstein

JOSEPH S LAWRENCE
Executive Officer

ROCKLAND COUNTY

The June meeting of the Medical Society of the County of Rockland was held at the Rockland Country Club, Sparkill, New York, on Wednesday, June 24, 1931 Approximately forty-eight members were present, including honorary members and guests

Dr Samuel G Gant, former professor of Proctology, Post-Graduate Hospital, New York City, was the speaker for the day The doctor presented many phases of his important and fascinating subject "Practical Proctology" which proved to be of considerable interest to the general practitioner

Doctor Gant also provided the entertainment by telling stories and performing sleight of hand tricks The doctor proved as eminent in entertaining as he is in his profession

The treasurer reported 53 members in the Society, nearly all of whom are in good standing

Two new members were elected to the Society

A delightful dinner was provided by Doctor George A Leitner, who acted as host

The afternoon continued in gaiety and fun which gave the members of the Society an all-round good time

W. J RYAN, *Secretary*

THE DAILY PRESS

PREDICTING POPULATIONS

An editorial writer in the New York *Herald Tribune* of June 23, is evidently in sympathy with his associate, the cartoonist, whose drawing on "Birth-Control" was copied in the May fifteenth issue of this Journal. The writer, in discussing predictions of populations, says:

"Scientists and super-scientists and pseudo-scientists are constantly warning the world that the human race is dying out or overbreeding, or that the white race is about to be submerged, or that the cultured upper classes are not perpetuating themselves, and portraying a grim, dark future for poor mankind. The various ebullitions in the last few days of what is gloriously called the International Union for the Scientific Investigation of Population Problems are no better and no worse than the usual run. The fact is that there is not yet any such thing as a 'science of population.'

"We refuse to pale with alarm. The so-called upper classes have probably been dying out consistently since the origin of the human race. Wealth and leisure, which might be expected to make many children a simpler problem, have never been an inducement to large families. So far as the historians can peer into the recesses of history, they have always led rather to restriction upon multiplication; and the result has not yet been disastrous for human society. Out of some mysterious wells of human talent emerge ever new strains to utilize new opportunities; and the evidence is not unanimous that it is wholly a misfortune that the sons of wealth and genius do not always reproduce their kind. There are mysteries here that science has not yet pulmbed; possibilities of human development which have not been tapped. The true scientist stands baffled and a little awed before the enigma which others call the science of population."

WELLS OF INSPIRATION

James J. Montague, in his column "More Truth than Poetry," in the *New York Herald Tribune* of June 10, has the following verses suggested by a news note that Dante and other geniuses were in the habit of meeting in the local drug stores:

"In the days when there wasn't an 'anti'
To awaken the national ire—
In the time when the late Mr. Dante
Plucked his lilting and lyrical lyre,
If of themes for an epic his bosom was bare,
And he felt like a nip of good hock,
To the old corner drug store he used to repair
For a neighborly chat with the 'doc,'
And when he returned to his quiet abode
He would pick up his stylus and turn out an ode.

"John Keats, in his meek adolescence—
'Ere he wrote about song birds and elves—
Knew the name of each extract and essence
That the drug store contained on its shelves.
He was skilled and adept in the mixing of pills
For the shoemaker, blacksmith or cop,
And he first heard the nightingale's nocturnal trills
Through the door of his little old shop.
And there mandragora and poppy and thyme
He mingled, while clothing his fancies in rhyme.

"Today not a measure comes rippling
From the depths of the pharmacist's store.
For the habit of neighborly tippling
Is practiced within it no more.
And perhaps that is why that so rarely one meets
With the songs that so limpidly flow
As they did in the eras when Dante and Keats
Plied their pens, in the long, long ago.
Times change with the ages, alas, and today
No undying classic the drug stores purvey."

SEWAGE OF NEW YORK CITY

New York is often quoted as using one of the most primitive of all methods of sewage disposal —that of emptying it into the immense bodies of running waters which surround and penetrate the city What might have been the condition of the City is set forth in the following editorial in the *New York Herald Tribune* of July 7

"New York began with an unrivaled harbor, with many miles of splendid watercourses running everywhere through the territory upon which the city now stands with shores which could have been preserved for park and residential ends with countless natural beauties which could have been woven into a city plan fully adequate for supporting not only her present but her future population, but there has never been a plan and most of the opportunity has been wasted

"The best that we can do now is to rescue as much as possible from the consequences of lack of foresight and regulation Sewage and garbage disposal is an obvious way to begin, we cannot recover the gentle meadows of Hoboken or the sylvan shores of the East River, but it is possible to purify the open sewer which we have made of the waters amid which we pass our lives, and which is defiling not only the city but the beaches in New Jersey or along the Sound where we might otherwise take refuge"

The City is now developing a consistent plan of sewage disposal, and is building a first great unit on Ward's Island in the upper East River Concerning it the editorial continues

"Breaking ground for a sewage reduction plant may not be among the most inspiring of ceremonies, nevertheless, if the pent up millions of New York know what is good for them, they will hail the rites to be undertaken this afternoon on Ward's Island as a ray of hope amid an almost stygian darkness Even the immense Ward's Island plant will not do everything, for it represents only the beginning of a full program which is not expected to be finished until 1960 But it is something, and if we have to wait thirty years for a proper answer to the sewage problem, we can at least use the time in attacking the problems of garbage disposal and other forms of city planning which must be met before New York becomes the kind of city that it ought to be

STICKY STREETS

Wherever asphalt tar is used on roads there will be trouble with its sticky surface on hot days The newspapers recently described the plight of a cat whose feet were held tight by the tar on a sticky road A similar fate befell a woman according to the following editorial in the *New York Herald Tribune* of July 6

"New Yorkers endure a lot of inconvenience without a word of complaint, which no doubt explains why it took a near accident to bring out the fact that sticky streets are an unnecessary evil A few days ago a woman narrowly escaped being run down by a taxicab at a crossing when her shoes stuck fast in the soft tar She extricated herself finally, but her shoes were ruined Her complaint to the Street Department elicited the information that gangs of men with sand carts are supposed to go about the streets and sprinkle sand on the sticky places The wonder is that more protests have not been forthcoming from women at least, whose slender heeled shoes sink into the tar with disastrous results Dodging traffic is enough of a problem, without having it made more difficult by a sticky impediment By all means let us have the tar sprinkled with sand, the sooner the better"

HITCH HIKERS

Since physicians spend much of their time on the public roads, they will approve the laws described in the following editorial in the *New York Sun* of July 2

"The campaign against hitch hikers goes steadily on In Pennsylvania they are now liable to a fine of $2 or imprisonment for one day, under a provision of the amendments to the State's motor vehicle code which Governor Pinchot has approved A year ago Governor Roosevelt signed the Bartholomew bill, making it unlawful for a person to stand in a roadway for the purpose of stopping a private vehicle to solicit a ride Other states have similar laws A bill introduced in the Legislature at Concord, New Hampshire, provided that all hitch hikers using the highways of the State must pay $3 20 to register with the Secretary of State and $2 30 for a license from the Motor Vehicle Commissioner Other provisions were that they must carry a metal sign announcing their proposed destination, be provided with an emergency can containing one gallon of gasoline for automobiles in difficulties, and be equipped with two head lights and a tail-light if traveling at night Obviously nine nomads out of ten would trust to their own legs rather than comply with such conditions"

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

HEART DISEASE. By PAUL DUDLEY WHITE, M.D. Octavo of 931 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $12.00. (Macmillan Medical Monographs.)

RESISTANCE TO INFECTIOUS DISEASES. An exposition of the biological phenomena underlying the occurrence of infection and the recovery of the animal body from infectious disease, with a consideration of the principles underlying specific diagnosis and therapeutic measures. By HANS ZINSSER, M.D. Fourth edition. Octavo of 651 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $7.00.

TEXT-BOOK OF PHYSICAL THERAPY. By WILLIAM BENHAM SNOW, M.D. Volume I. Octavo of 708 pages, illustrated. New York, Scientific Authors' Publishing Company, 1931. Cloth, $10.00.

MEDICAL ADMINISTRATION OF TEACHING HOSPITALS. By EMMET B. BAY, M.D. Octavo of 136 pages. Chicago, The University of Chicago Press, 1931. Cloth, $2.00. (Medical Economics Series.)

THE SEX FACTOR IN MARRIAGE. A book for those who are or are about to be married. By HELENA WRIGHT, M.B., B.S. 12mo of 122 pages. New York, The Vanguard Press, 1931. Cloth, $2.00.

THE MODERN HOSPITAL YEAR BOOK: The Hospital Reference Book, 10th edition, 1930. Quarto of 973 pages, illustrated. Chicago, The Modern Hospital Publishing Co., Inc., 1930. Cloth, $2.50.

TREATMENT OF INJURY BY THE GENERAL PRACTITIONER. By CLAY RAY MURRAY, M.D., F.A.C.S. Two volumes. 12mo of 412 pages, illustrated. New York and London, Harper & Brothers, 1931. Cloth, $5.00. (Harper's Medical Monographs.)

RECENT ADVANCES IN THE STUDY OF THE PSYCHONEUROSES. By MILLAIS CULPIN, M.D., F.R.C.S. Octavo of 348 pages. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50. (The Recent Advances Series.)

FOOD ALLERGY: Its Manifestations, Diagnosis and Treatment with a General Discussion of Bronchial Asthma. By ALBERT H. ROWE, M.S., M.D. Octavo of 442 pages. Philadelphia, Lea & Febiger, 1931. Cloth, $5.00.

THOMSON & MILES' MANUAL OF SURGERY. By ALEXANDER MILES, M.D., LL.D., and D. P. D. WILKIE, M.D., F.R.C.S. Eighth edition. Volume 1, General Surgery. 12mo of 574 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $3.80. (Oxford Medical Publications.)

BREAST-FEEDING. By MARGARET EMSLIE, M.B., Ch.B. 12mo of 142 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $2.00. (Oxford Medical Publications.)

THE SIGNIFICANCE OF WATERBONE TYPHOID FEVER OUTBREAKS, 1920-1930. By ABEL WOLMAN and ARTHUR E. GORMAN. Octavo of 82 pages. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $2.00.

FIGHTING DISEASE WITH DRUGS: The Story of Pharmacy. A Symposium. Edited by JOHN C. KRANTZ, JR. Octavo of 230 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $2.00.

HEALTH ON THE FARM AND IN THE VILLAGE. A Review and Evaluation of the Cattaraugus County Health Demonstration with Special Reference to Its Lessons for Other Rural Areas. By C.-E. A. WINSLOW, Dr.P.H. Octavo of 281 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $1.00.

TEXT-BOOK OF HISTOLOGY for Medical and Dental Students. By EUGENE C. PIETTE, M.D. Octavo of 466 pages, illustrated. Philadelphia, F. A. Davis Company, 1931. Cloth, $4.50.

MEDICAL JURISPRUDENCE. By ALFRED W. HERZOG, Ph.B., A.M. Quarto of 1051 pages. Indianapolis, The Bobbs-Merrill Company, 1931. Cloth, $15.00.

INSOMNIA: An Outline for the Practitioner. By H. CRICHTON-MILLER, M.A., M.D. Octavo of 172 pages. London, Edward Arnold & Company; New York, Longmans, Green & Company, 1930. Cloth, $4.20.

HYPERTENSION AND NEPHRITIS. By ARTHUR M. FISHBERG, M.D. Second edition. Octavo of 619 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $6.50.

THE DOCTOR AND HIS INVESTMENTS. Financial Policy and Technique for the Physician. By MERRYLE STANLEY RUKEYSER, B.Lit., M.A. 12mo of 330 pages. Philadelphia, P. Blakiston's Son & Co., Inc. [1931]. Cloth, $2.50.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 14, No. 6, May, 1931. (New York Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, $16.00 net; paper, $12.00 net.

INTERNATIONAL STUDIES on the Relation between the Private and Official Practice of Medicine with Special Reference to the Prevention of Disease conducted for The Milbank Memorial Fund. By SIR ARTHUR NEWSHOLME, K.C.B., M.D. Volume 2. Octavo of 249 pages. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $4.00.

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. By Various Authors. (Prepared under the direction of the Medical Research Council). Volume VIII. Octavo of 390 pages, illustrated. London, His Majesty's Stationery Office, 1931. Cloth, £8-8-0 a set; £1-1-0 each.

ABDOMINAL PAIN. By JOHN MORLEY, Ch.M., F.R.C.S. Octavo of 191 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $3.50.

PRACTICAL METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES, for Medical Practitioners and Students. By DAVID LEES, D.S.O., M.A. Second edition. 12mo of 634 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $5.00.
